# THE AMERICAN EPHEMERIS AND NAUTICAL ALMANAC

FOR THE YEAR 1960

## WASHINGTON

Issued by the  
Nautical Almanac Office  
United States  
Naval Observatory  
by direction of the  
Secretary of the Navy  
and under the  
authority of Congress

## LONDON

Issued by  
Her Majesty's  
Nautical Almanac Office  
by order of the  
Lords Commissioners  
of the Admiralty  
under the title  
*The Astronomical Ephemeris*

## PREFACE

Beginning with the editions for 1960, *The American Ephemeris and Nautical Almanac* issued by the Nautical Almanac Office, United States Naval Observatory, and *The Astronomical Ephemeris* issued by H.M. Nautical Almanac Office, Royal Greenwich Observatory, are now unified. With the exception of the introductory pages i, ii, vi, and viii the two publications are identical; they are printed separately in the two countries, from reproducible material prepared partly in the United States of America and partly in the United Kingdom.

The title *The Astronomical Ephemeris* replaces, without loss of continuity of content, the previous title of *The Nautical Almanac and Astronomical Ephemeris* (usually abbreviated to the *Nautical Almanac*), which was introduced by Nevil Maskelyne for the original British edition of 1767; the title *The Nautical Almanac* will henceforward be used, in both the United Kingdom and the United States, for the unified edition of the Almanac for surface navigation previously entitled *The Abridged Nautical Almanac* and *The American Nautical Almanac* respectively.

The unification has not required any substantial changes in either publication; but a number of revisions have been made to increase the precision and improve the usefulness. The contents are fully described in the *Explanation* at the end of the volume. The principal changes from the immediately preceding volumes are for the purpose of conforming to the recommendations of the Paris Conference on Astronomical Constants in 1950 and to the resolutions of the International Astronomical Union at the Zürich Assembly in 1948, the Rome Assembly in 1952, and the Dublin Assembly in 1955.

In accordance with these resolutions, the designation Ephemeris Time is adopted for the argument of the fundamental ephemerides of the Sun, Moon, and planets. In nearly all the other ephemerides, the argument is Universal Time, obtained from an extrapolated value of the difference between the two measures of time. The longitude, latitude, and parallax of the Moon are calculated directly from theoretical expressions derived by amending Brown's expressions in order to obtain a strictly gravitational ephemeris expressed in the same measure of time as defined by Newcomb's *Tables of the Sun*, and by including aberration; the coordinates of the Moon are tabulated to one more decimal than in preceding volumes. The ephemerides of Jupiter, Saturn, Uranus, Neptune, and Pluto are calculated from rectangular heliocentric coordinates obtained by numerical integration; and the geocentric right ascensions and declinations are tabulated to one more decimal than in preceding volumes. In the ephemeris for physical observations of Mars, the period of rotation determined by Ashbrook is adopted. The ephemeris of the fifth satellite of Jupiter is computed from the orbital elements determined by van Woerkom.

The nutation in longitude and obliquity is calculated from the expressions obtained by retaining all terms with coefficients as great as  $0''.0002$  in the developments derived by Woolard; and in the ephemerides of the Sun, Moon, and planets, the short-period terms of nutation, defined as terms with periods of less than 100 days, are fully included in all the tabular quantities. The Day Numbers for the calculation of apparent places of stars are for reductions from the mean place at the *nearest* beginning of a year, instead of always at the beginning of the

current year. The Day Number  $A$  is re-defined, as the product of the former value by the annual precession in declination, in order to express it in seconds of arc; and the Day Numbers  $C$  and  $D$  are computed from the actual disturbed velocity of the Earth referred to the centre of mass of the solar system. The Day Numbers are tabulated to one more decimal than in preceding volumes.

These fundamental revisions are accompanied by many changes in the details of form and arrangement from the immediately preceding volumes, and by some additions and omissions. The principal omissions from the *American Ephemeris* are: the elements and predictions of occultations; the local circumstances of solar eclipses and of the transit of Mercury; the former list of mean places of 1551 standard stars; the Day Numbers for Greenwich sidereal  $12^h$  without short-period terms; and the former tables relating to *Polaris*. Omissions from the former *Nautical Almanac* are: the ephemerides of the Sun, Moon, and planets at transit at Greenwich; the apparent places of occulted stars and predictions of occultations; and the daily times of sunrise and sunset.

The additions are: Day Numbers, denoted by  $J$  and  $J'$ , for calculating apparent places of stars to the second order; predictions of penumbral lunar eclipses when any occur; an ephemeris for physical observations of Saturn; and a list of radio observatories. The tables from the former *Nautical Almanac* for approximate reductions of positions from the mean equinox of 1950.0 to the true equinox of date, and for differential aberration, precession, and nutation, not previously included in the *American Ephemeris*, have been retained.

Precise transit ephemerides, which have not been printed in the *American Ephemeris* since 1950, are not required for finding purposes, nor for the comparison of observation with theory; the transit ephemerides that may be necessary for setting meridian instruments, and for reduction of the observations, may readily be computed as needed where observations are made.

Instead of the list of mean places of stars omitted from the *American Ephemeris*, the shorter list, with less precise positions, from the former *Nautical Almanac* is retained; and in place of the omitted *Polaris* tables, a single table for determining latitude and azimuth from *Polaris*, formerly Table XIV in the *Nautical Almanac*, is included.

In place of the omitted local circumstances of solar eclipses, the eclipse maps are on a larger scale when needed. An adequate map is likewise included for the transit of Mercury. The representations of the configurations of the four principal satellites of Jupiter, which were previously given for particular times, differing in the two countries, have been replaced by a series of diagrams enabling the positions to be estimated at any time.

Although no data are now included in respect of occultations of stars by the Moon, the occultation programme of H. M. Nautical Almanac Office continues unchanged. Arrangements for the publication of predictions have been made as follows: for stations in the United States and Canada in *Sky and Telescope*; and for other British stations in the *Handbook of the British Astronomical Association*. Machine copies of predictions for any of the 70 stations for which predictions are made, or of the elements of occultations, may be obtained on request.

The apparent places of the 1535 stars in the FK3 are available in *Apparent Places of Fundamental Stars*, published annually under the auspices of the International Astronomical Union, as from 1960 by the Astronomisches Rechen-Institut

in Heidelberg. The apparent places are tabulated continuously at intervals of ten upper transits at Greenwich; and the mean places will be listed in at least every tenth annual volume. Each volume also contains, for purposes of record, the Besselian Day Numbers at 12<sup>h</sup> Greenwich sidereal time, without short-period terms, with which the apparent places are calculated.

The star ephemerides that are needed by surveyors, including the tables relating to *Polaris*, are available in *The Ephemeris* published by the U.S. Bureau of Land Management, and in *The Star Almanac for Land Surveyors* prepared by H. M. Nautical Almanac Office and published by H. M. Stationery Office.

An *Explanatory Supplement* to this volume, to be published by H. M. Stationery Office in London, is in course of preparation, but is unlikely to be available before July 1959. This will contain detailed explanations of the data included in this volume, together with a derivation and numerical illustrations, as well as useful permanent tables that are now omitted.

By international agreement, the basic calculations for this volume, and for other astronomical ephemerides such as *Apparent Places of Fundamental Stars*, and *Ephemerides of Minor Planets*, are shared between the ephemeris offices of a number of countries. Contributions, in addition to those listed below, are made by the Astronomisches Rechen-Institut in Heidelberg, the Institute for Theoretical Astronomy in Leningrad, and the offices of the *Connaissance des Temps* in Paris and the *Almanaque Nautico* in San Fernando.

The ephemeris of Universal and Sidereal Times, the ephemerides of the Sun, Moon, Mercury, Venus, Mars, Jupiter, Saturn, Uranus, and Neptune, the geocentric ephemerides of Ceres, Pallas, Juno, Vesta, and Pluto, the nutation in longitude and obliquity, the Day Numbers, and the Phenomena, are prepared in H. M. Nautical Almanac Office.

The conjunctions, phenomena, and configurations of Satellites I–IV of Jupiter are received from the office of the *Connaissance des Temps*. The data for Table II are received from the Astronomisches Rechen-Institut.

The remaining data in the volume are prepared in the Nautical Almanac Office, United States Naval Observatory, namely: mean places of stars; eclipses of the Sun and Moon, and transit of Mercury; ephemerides for physical observations of the Sun, Moon, and planets; ephemerides of the satellites of Mars, Saturn, Uranus, and Neptune, and of Satellites V, VI, and VII of Jupiter, and of the rings of Saturn; local mean times of moonrise and moonset; Tables III, IV, and VI.

This volume was prepared jointly by H. M. Nautical Almanac Office, Royal Greenwich Observatory, under the immediate supervision of D. H. Sadler, and by the Nautical Almanac Office, United States Naval Observatory, under the immediate supervision of G. M. Clemence and Edgar W. Woolard.

November, 1957

The calculations for the principal ephemerides prepared in the Nautical Almanac Office, United States Naval Observatory, were made by the following members of the staff and their assistants: mean places of stars, MARIAN H. SHARPLESS; eclipses of the Sun and the Moon, and the transit of Mercury, SIMONE DARO GOSSNER; ephemerides for physical observations of the Sun, Moon, and planets, and ephemerides of the satellites of Mars, Saturn, Uranus, and Neptune, satellites VI and VII of Jupiter, and the rings of Saturn, CHARLOTTE KRAMPE; local mean time of moonrise and moonset, RALPH F. HAUPT. The maps of solar eclipses and the transit of Mercury, and the diagrams of the satellite orbits and the configurations of satellites I-IV of Jupiter, were prepared by SIMONE DARO GOSSNER. The interpolation tables, Tables XIII-XVII, were designed by G. A. WILKINS.

## ERRATA

*The American Ephemeris, 1959*

Page

501 Third line from top,  $\Delta Z$ .... for + 244 read - 244*The American Ephemeris, 1960*

- 177 The elements of the outer planets have been calculated using the Gaussian constant  $k$  instead of  $k \sqrt{1+m}$ ; corrected values are given on page xii.
- 210-235 Small corrections to the printed ephemerides of the planets are given on page ix.
- 286, 287 The second-order day numbers on these pages apply to northern declinations only. Values for southern declinations are given on pages x and xi.

In interpolating the geometric ephemerides of the planets for light-time, in order to correct for aberration, the second-difference correction in Stirling's formula was applied erroneously. The following corrections are to be applied to the printed ephemerides.

The quantity  $J$  is given in this table in units of 0<sup>s</sup>.00001, and is to be multiplied by  $\tan^2 \delta$  to give the second-order correction in the calculation of the apparent right ascension of a star.

The complete formula is :

$$a = a_0 + \tau \mu_a + Aa + Bb + Cc + Dd + E + J \tan^2 \delta$$

The Julian Day begins at noon.

The fraction of the year  $\tau$ , measured from the beginning of the Besselian fictitious year (1960.0 or 1960 January 1<sup>d</sup>.345), is given on pages 266-280.

# PHENOMENA, 1960

## GEOCENTRIC PHENOMENA IN U.T.

### MERCURY

Superior conjunction ...	Jan. 26	May 17	Aug. 30
Greatest elongation East	Feb. 23 (18°)	June 19 (25°)	Oct. 15 (25°)
Stationary ... ..	Mar. 1	July 2	Oct. 27
Inferior conjunction ...	Mar. 10	July 17	Nov. 7
Stationary ... ..	Mar. 23	July 27	Nov. 16
Greatest elongation West	Apr. 7 (28°)	Aug. 5 (19°)	Nov. 24 (20°)

### VENUS

Superior conjunction ... June 22

### EARTH

Perihelion ...	Jan. 4	Equinoxes ...	Mar. 20 <sup>d</sup> 14 <sup>h</sup> 43 <sup>m</sup>	Sept. 23 <sup>d</sup> 01 <sup>h</sup> 00 <sup>m</sup>
Aphelion ...	July 2	Solstices ...	June 21 09 43	Dec. 21 20 27

### SUPERIOR PLANETS

	Stationary	Opposition	Stationary	Conjunction
Mars ... ..	Nov. 21	Dec. 30	—	—
Jupiter ... ..	Apr. 20	June 20	Aug. 20	—
Saturn ... ..	Apr. 27	July 7	Sept. 15	—
Uranus ... ..	Dec. 1	Feb. 8	Apr. 24	Aug. 14
Neptune ... ..	Feb. 10	Apr. 28	July 18	Nov. 1
Pluto ... ..	Dec. 16	Feb. 24	May 19	Aug. 29

### HELIOCENTRIC PHENOMENA

	Perihelion	Aphelion	Ascending Node	Greatest Lat. North	Descending Node	Greatest Lat. South
Mercury	—	Jan. 9	—	—	—	Jan. 30
	Feb. 22	Apr. 6	Feb. 18	Mar. 4	Mar. 27	Apr. 27
	May 20	July 3	May 16	May 31	June 23	July 24
	Aug. 16	Sept. 29	Aug. 12	Aug. 27	Sept. 19	Oct. 20
	Nov. 12	Dec. 26	Nov. 8	Nov. 23	Dec. 16	—
Venus	—	Mar. 26	—	—	Feb. 21	Apr. 18
	July 17	Nov. 6	June 13	Aug. 7	Oct. 2	Nov. 28
Mars	May 26	—	Sept. 25	—	—	May 1

Jupiter : Descending Node ... Nov. 4  
 Saturn, Uranus, Neptune, Pluto : None

### ECLIPSES

Mar. 13	Total eclipse of the Moon	Americas, Arctic, Pacific Ocean, Australasia, E. Asia
Mar. 27	Partial eclipse of the Sun	S. Australia, Antarctica
Sept. 5	Total eclipse of the Moon	Americas, Antarctica, Pacific Ocean, India, E. Asia
Sept. 20-21	Partial eclipse of the Sun	E. Siberia, N. America
Nov. 7	Transit of Mercury	Europe, Africa, Americas, Pacific Ocean

## OCCULTATIONS OF PLANETS AND BRIGHT STARS

Date	Body	Area of Visibility	Date	Body	Area of Visibility
Jan. 10 09	<i>Aldebaran</i>	E. Asia, N. America	June 22 04	<i>Aldebaran</i>	N. Africa, Europe, Asia
Feb. 6 16	<i>Aldebaran</i>	Europe, N. Africa, Asia	July 19 10	<i>Aldebaran</i>	N. America, Europe, N. Africa
Mar. 5 00	<i>Aldebaran</i>	N. America, W. Europe	Aug. 15 17	<i>Aldebaran</i>	Pacific, Americas
Mar. 25 12	Mercury	America, Europe, N. Africa	Aug. 23 22	Venus	Antarctica
Apr. 1 08	<i>Aldebaran</i>	Asia	Sept. 12 01	<i>Aldebaran</i>	North Africa, Asia
Apr. 24 01	Mercury	Central Russia, N. Pole	Oct. 9 09	<i>Aldebaran</i>	North America, Iberia
Apr. 24 13	Venus	S. America, S. Africa	Nov. 5 18	<i>Aldebaran</i>	Asia
Apr. 28 16	<i>Aldebaran</i>	N. America, Europe, N. Africa	Dec. 3 01	<i>Aldebaran</i>	N. America, Europe, N. Africa, Asia
May 20 22	Mars	E. Indies, N. Australia, Pacific	Dec. 30 07	<i>Aldebaran</i>	North America

## DIARY

Jan. 0 14	Ceres in conjunction with Sun	Feb. 17 03	Venus 1°·1 N. of Mars

Daily motion	$0^{\circ}.985647$	$0^{\circ}.985600$		
Epoch 1960 January 1.0				
Mean longitude of perigee	$\Gamma$	$282^{\circ}.25248$		
Eccentricity	$e$	$0.0167259$		
			For reduction from	
			1960.0 to 1950.0	1950.0 to 1960.0
			$\zeta_0 \dots$	$-3' 50''.51$ $= -15^{\circ}.367$
			$z \dots$	$+3' 50''.50$ $+15^{\circ}.367$
				$-3' 50''.50$ $= -15^{\circ}.367$
			$\sin \theta$	$-0.000\ 97167$ $+0.000\ 97167$
			$\tan \frac{1}{2} \theta$	$-0.000\ 48584$ $+0.000\ 48584$
			$M^s$	$-30^{\circ}.734$ $+30^{\circ}.734$
			$N^s$	$-13^{\circ}.361$ $+13^{\circ}.361$
			$N''$	$-200''.42$ $+200''.42$
			$a \dots$	$-8' 22''.69$ $+8' 22''.69$
				$= -0^{\circ}.13964$ $+0^{\circ}.13964$
			$b \dots$	$-4''.71$ $+4''.71$
				$= -0^{\circ}.001308$ $+0^{\circ}.001308$
			$c \dots$	$+5^{\circ}\ 28'.6$ $+5^{\circ}\ 37'.0$
				$= +5^{\circ}.477$ $+5^{\circ}.617$
			Formulae:	
			$\alpha = \alpha_0 + M + N \sin \alpha_m \tan \delta_m$	
			$\delta = \delta_0 + N \cos \alpha_m$	
			$\lambda = \lambda_0 + a - b \cos(\lambda_0 + c) \tan \beta_0$	
			$\beta = \beta_0 + b \sin(\lambda_0 + c)$	
			$\Omega = \Omega_0 + a - b \sin(\Omega_0 + c) \cot i_0$	
			$i = i_0 + b \cos(\Omega_0 + c)$	
			$\omega = \omega_0 + b \sin(\Omega_0 + c) \operatorname{cosec} i_0$	
			where $\alpha_m, \delta_m$ are for the mean epoch.

The quantity  $J$  is given in this table in units of 0<sup>s</sup>.00001, and is to be multiplied by  $\tan^2 \delta$  to give the second-order correction in the calculation of the apparent right ascension of a star.

The complete formula is :

$$\alpha = \alpha_0 + \tau\mu_\alpha + Aa + Bb + Cc + Dd + E + J \tan^2 \delta$$

There will be four eclipses, two of the Sun and two of the Moon.

I March 13	Total eclipse of the Moon
II March 27	Partial eclipse of the Sun
III September 5	Total eclipse of the Moon
IV September 20-21	Partial eclipse of the Sun

A correction of  $-0''.5$  has been applied to the tabular latitude of the Moon. This correction is given below in the form of corrections to the right ascension and declination of the Moon.

	d	$\Delta\alpha$	$\Delta\delta$
March	13	$- 0''.20$	$- 0''.46$
March	27	$+ 0.20$	$- 0.46$
September	5	$+ 0.19$	$- 0.46$
September	20-21	$- 0.20$	$- 0.46$

The arguments are given in Ephemeris Time. The hour angle  $\mu$  and the longitudes are referred to the ephemeris meridian. Once the value of  $\Delta T$  is known, the data on these pages may be expressed in terms of Universal Time in the following manner:

Convert all arguments into Universal Time by the relation  $U.T. = E.T. - \Delta T$ .

Apply the correction  $-1.0027 \Delta T$  to  $\mu$  and to the longitudes, in order to refer them to the meridian of Greenwich, remembering that a second of time is equivalent to 15 seconds of arc.

Leave all other quantities unchanged.

I.—*Total Eclipse of the Moon*, March 13; the beginning visible in North America, South America, the Pacific Ocean except the southwestern part, the northeastern tip of Asia, the Atlantic Ocean except the southeastern part, the west coasts of Europe and of North Africa, and parts of Antarctica; the end visible in North America except the northeastern part, the western half of South America, the Pacific Ocean, Australia except the west coast, New Zealand, the east coast of Asia, and parts of Antarctica.

# PARTIAL SOLAR ECLIPSE OF SEPTEMBER 20-21, 1960

A transit of Mercury over the disk of the Sun will occur on November 7.

A correction of  $-0''.90$  has been applied to the tabular true orbital longitude of Mercury,  $+1''.20$  to the longitude of the node, and  $+0.000\ 0026$  to the logarithm of the radius vector.

#### ELEMENTS OF THE TRANSIT

E.T. of conjunction in apparent geocentric longitude, November 7<sup>d</sup> 16<sup>b</sup> 38<sup>m</sup> 36<sup>s</sup>.54

Apparent longitude of Sun	225 16 33.15	Hourly motion	+2 30.59
Apparent longitude of Mercury	225 16 33.15	Hourly motion	-3 18.52
Latitude of Sun	- 0 00.61	Hourly motion	0 00.00
Latitude of Mercury	- 8 55.95	Hourly motion	+0 51.79
Equatorial hor. par. of Sun	8.88	True semidiameter of Sun	16 08.68
Equatorial hor. par. of Mercury	13.03	True semidiameter of Mercury	4.95

#### GEOCENTRIC PHASES

	E.T.	Position Angle $P$	Mercury being in the Zenith in Ephemeris Longitude	Latitude
	d h m s	°	° ' "	° ' "
Ingress, exterior contact	Nov. 7 14 34 33.4	148.3	+ 42 34	-16 37
Ingress, interior contact	7 14 36 33.8	148.7	+ 43 04	-16 37
Least angular distance	7 16 53 35.2		+ 77 32	-16 33
Egress, interior contact	7 19 10 40.8	262.1	+112 01	-16 29
Egress, exterior contact	7 19 12 41.2	262.5	+112 31	-16 29

Least angular distance 8'48"1

The Universal Times of the four contacts for any point on the surface of the Earth may be computed from the four following formulae, in which  $\rho$  denotes the radius of the Earth at that point,  $\phi'$  the geocentric latitude, and  $\lambda$  the longitude west from Greenwich;  $T^I$  and  $T^{II}$  are respectively the times of exterior and interior contacts at ingress,  $T^{III}$  and  $T^{IV}$  at egress.

$$\begin{aligned}
 T^I &= 14\ 34\ 33.4 + 41.17\ \rho \sin \phi' - 29.30\ \rho \cos \phi' \cos (72\ 14.8 + \lambda + 1.0027\Delta T) - \Delta T \\
 T^{II} &= 14\ 36\ 33.8 + 41.51\ \rho \sin \phi' - 29.19\ \rho \cos \phi' \cos (72\ 04.3 + \lambda + 1.0027\Delta T) - \Delta T \\
 T^{III} &= 19\ 10\ 40.8 - 6.55\ \rho \sin \phi' + 50.04\ \rho \cos \phi' \cos (155\ 46.4 + \lambda + 1.0027\Delta T) - \Delta T \\
 T^{IV} &= 19\ 12\ 41.2 - 6.20\ \rho \sin \phi' + 49.87\ \rho \cos \phi' \cos (155\ 22.8 + \lambda + 1.0027\Delta T) - \Delta T
 \end{aligned}$$

The position angle  $P$  of the point of contact, reckoned from the north point of the limb of the Sun toward the east, may be taken as equal to its geocentric value given above. The position angle  $V$  of the point of contact, reckoned from the vertex of the limb of the Sun toward the east, is found by

$$V = P - C,$$

where  $C$ , the parallactic angle, is given by

$$\tan C = \frac{\cos \phi \sin h}{\sin \phi \cos \delta - \cos \phi \sin \delta \cos h},$$

in which  $\phi$  is the latitude of the place,  $\delta$  is the declination of the Sun and  $h$  is the local hour angle of the Sun;  $\sin C$  has the same algebraic sign as  $\sin h$ .

Accurate local circumstances may be calculated as follows.

Let the quantities  $u$ ,  $u'$ ,  $v$ ,  $v'$  and  $L$  be expressed in the form

$$A + B\rho \sin \phi' + \rho \cos \phi' (C \sin t + D \cos t),$$

where  $A$ ,  $B$ ,  $C$ ,  $D$  and  $t$  are tabulated below, with subscripts 1, 2, 3, 4 for the four contacts.

Let  $T_0$  be the Ephemeris Time of geocentric contact. The corresponding Universal Time  $T$  of local contact will be given by

$$T = T_0 + \tau - \Delta T,$$

where

$$\tau = 3600 \left[ \frac{L \cos \psi}{n} - \frac{uu' + vv'}{n^2} \right],$$

$$n^2 = u'^2 + v'^2,$$

$$\sin \psi = \frac{1}{nL} (uv' - u'v);$$

$\cos \psi$  is negative for ingress, positive for egress;  $\tau$  is in seconds.

	$u$	$u'$	$v$	$v'$	$L$
$A_1$	+6.65803	-0.53302	-7.58203	+3.61518	+10.09042
$B_1$	+0.03951	0	-0.01207	+0.00001	+ 0.00006

$B_2$	+0.03951	0	-0.01207	+0.00001	+ 0.00006
$C_2$	-0.01713	0	-0.02784	-0.00800	+ 0.00013
$D_2$	0	-0.00450	+0.03056	-0.00729	+ 0.00014
$A_3$	+4.19930	-0.53547	+9.09184	+3.63106	+10.01478
$B_3$	+0.03951	0	-0.01203	+0.00001	+ 0.00006
$C_3$	-0.01713	0	-0.02775	-0.00803	+ 0.00013
$D_3$	0	-0.00450	+0.03066	-0.00726	+ 0.00014
$A_4$	+4.18139	-0.53549	+9.21327	+3.63118	+10.11774
$B_4$	+0.03951	0	-0.01203	+0.00001	+ 0.00006
$C_4$	-0.01713	0	-0.02775	-0.00803	+ 0.00013
$D_4$	0	-0.00450	+0.03066	-0.00726	+ 0.00014

$$t_1 = 265 \quad 25.9 - \lambda - 1.0027 \Delta T$$

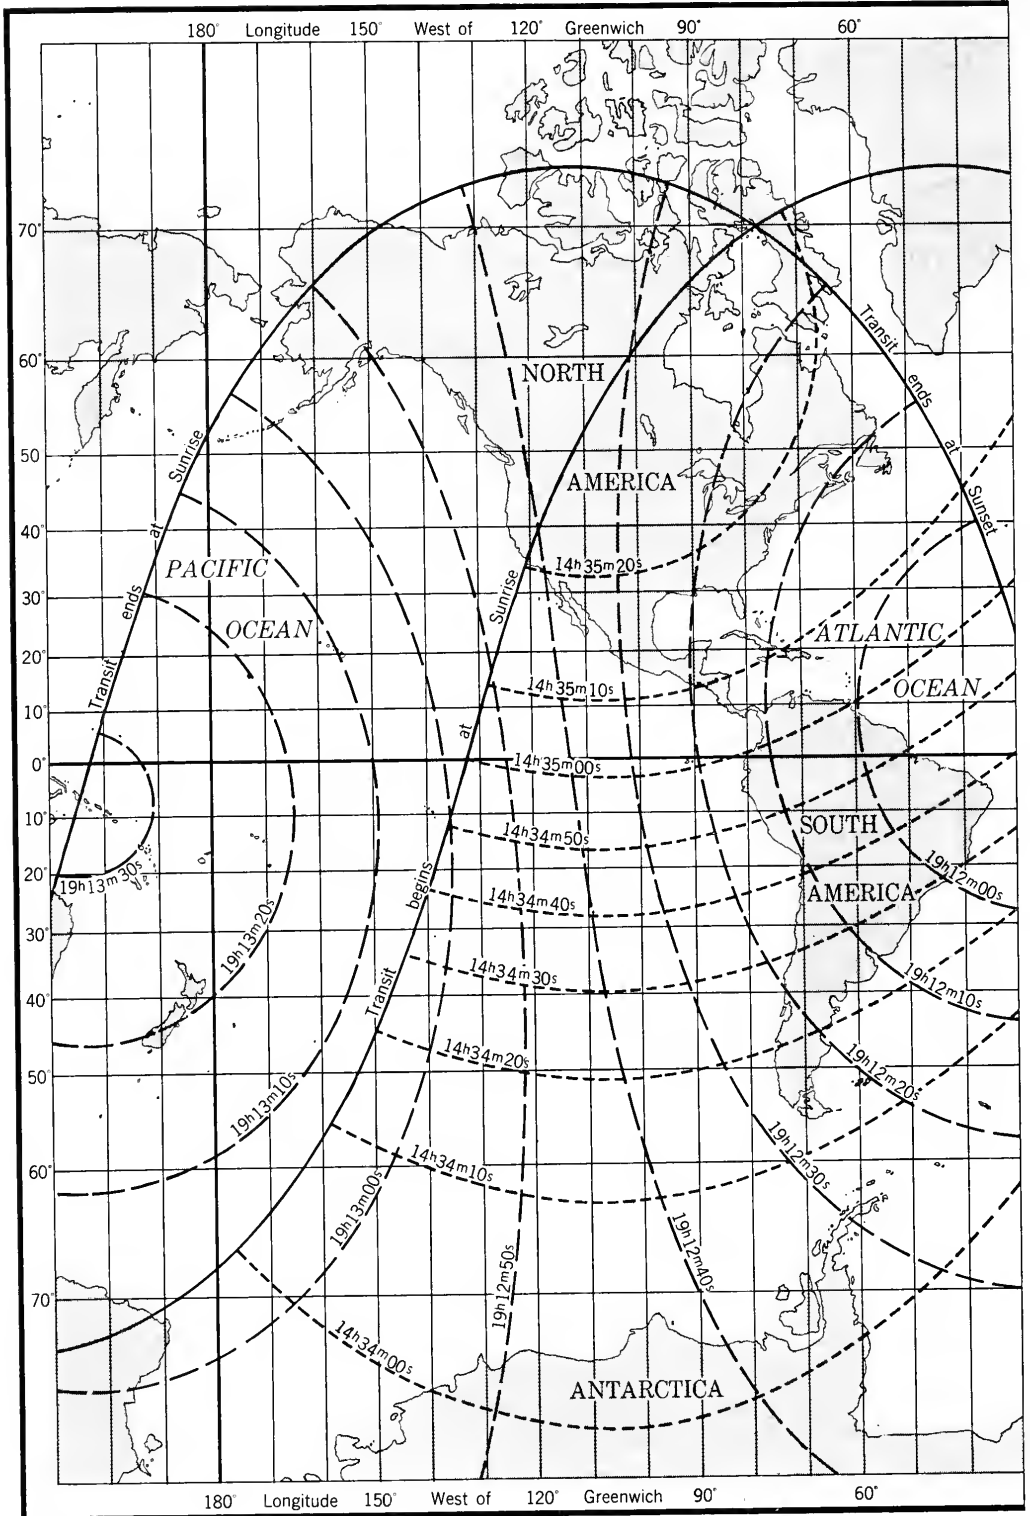

$$t_2 = 265 \quad 56.1 - \lambda - 1.0027 \Delta T$$

$$t_3 = 334 \quad 39.1 - \lambda - 1.0027 \Delta T$$

$$t_4 = 335 \quad 09.3 - \lambda - 1.0027 \Delta T$$

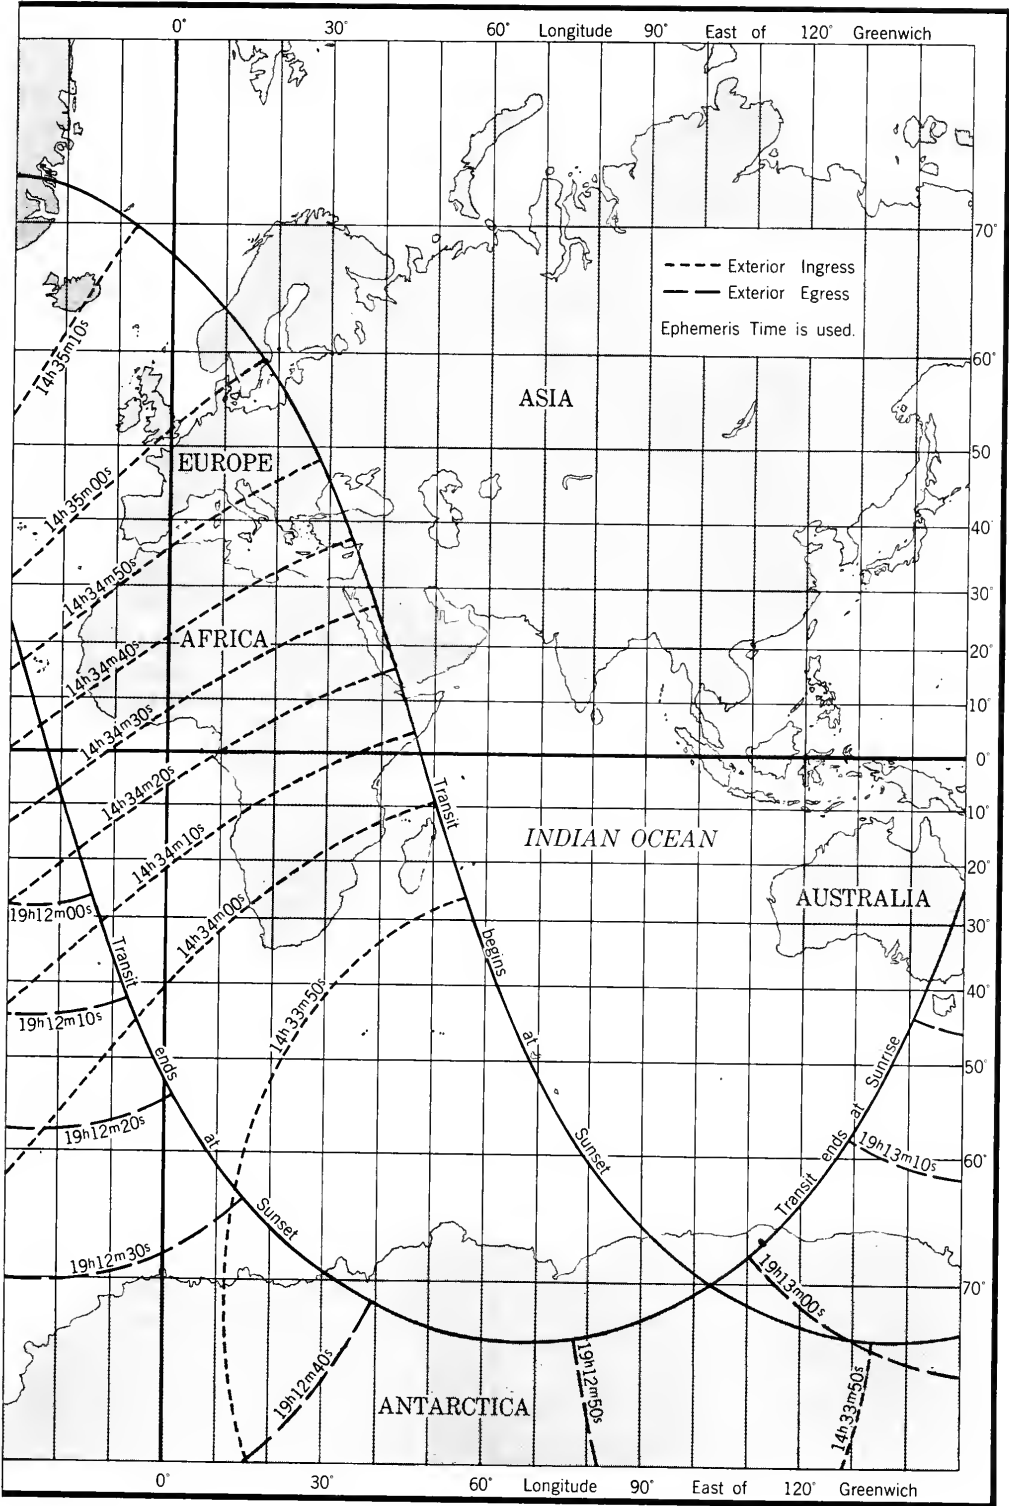

In general, the times of local contacts computed with this table will differ very little from those obtained with the formulae on the preceding page. However, for transits in which the least angular distance of Mercury and the Sun is almost equal to the semidiameter of the Sun, the difference may amount to several seconds.

*k* is the ratio of the area of the illuminated portion of the apparent disk to the area of the entire apparent disk regarded as circular.

*i* is the angle between the Sun and Earth, as seen from the planet.

Θ is the position angle of the midpoint of the bright limb, measured eastward from the north point of the disk.

*L* is the brilliancy of the disk. The unit of *L* is the amount of light received by an eye from a circular disk with the same albedo as the planet, subtending an angular radius of one second of arc, situated at distance unity from the Sun, and illuminated by the latter as the mean disk of the planet is illuminated.

If the horizontal parallax,  $\pi = 8''.80/\text{distance}$ , is known the parallax corrections are:

$$\Delta\alpha = \frac{1}{r} \pi \times \rho \cos \phi' \sin h \sec \delta \quad \Delta\delta = \pi \times \rho \cos \phi' (\tan \phi' \cos \delta - \cos h \sin \delta)$$

where  $h = \theta - \alpha$  and  $\theta$  = sidereal time at 0<sup>h</sup> + sidereal equivalent of U. T. -  $\lambda$

Otherwise add  $\Delta X = \Delta x$ ,  $\cos \theta$ ,  $\Delta Y = \Delta x$ ,  $\sin \theta$ ,  $\Delta Z$  to solar co-ordinates to eliminate parallax.

If the horizontal parallax,  $\pi=8''.80$ /distance, is known the parallax corrections are:

$$\Delta\alpha=\pi \times \rho \cos \phi' \sin h \sec \delta \quad \Delta\delta=\pi \times \rho \cos \phi' (\tan \phi' \cos \delta - \cos h \sin \delta)$$

where  $h=\theta-\alpha$  and  $\theta$ =sidereal time at 0<sup>h</sup>+sidereal equivalent of U.T.- $\lambda$

Otherwise add  $\Delta X=\Delta x_y \cos \theta$ ,  $\Delta Y=\Delta x_y \sin \theta$ ,  $\Delta Z$  to solar co-ordinates to eliminate parallax.

If the horizontal parallax,  $\pi=8''.80/\text{distance}$ , is known the parallax corrections are:

$$\Delta\alpha = \pi \times \rho \cos \phi' \sin h \sec \delta \quad \Delta\delta = \pi \times \rho \cos \phi' (\tan \phi' \cos \delta - \cos h \sin \delta)$$

where  $h = \theta - \alpha$  and  $\theta = \text{sidereal time at } 0^h + \text{sidereal equivalent of U.T.} - \lambda$

Otherwise add  $\Delta X = \Delta x_p \cos \theta$ ,  $\Delta Y = \Delta x_p \sin \theta$ ,  $\Delta Z$  to solar co-ordinates to eliminate parallax.

If the horizontal parallax,  $\pi = 8''.80/\text{distance}$ , is known the parallax corrections are:

$$\Delta\alpha = \pi \times \rho \cos \phi' \sin h \sec \delta \quad \Delta\delta = \pi \times \rho \cos \phi' (\tan \phi' \cos \delta - \cos h \sin \delta)$$

where  $h = \theta - \alpha$  and  $\theta$  = sidereal time at 0<sup>h</sup> + sidereal equivalent of U.T. -  $\lambda$

Otherwise add  $\Delta X = \Delta_{xy} \cos \theta$ ,  $\Delta Y = \Delta_{xy} \sin \theta$ ,  $\Delta Z$  to solar co-ordinates to eliminate parallax.

If the horizontal parallax,  $\pi=8''.80$ /distance, is known the parallax corrections are:

$$\Delta\alpha = \pi \times \rho \cos \phi' \sin h \sec \delta \quad \Delta\delta = \pi \times \rho \cos \phi' (\tan \phi' \cos \delta - \cos h \sin \delta)$$

where  $h=\theta-\alpha$  and  $\theta$ =sidereal time at 0<sup>h</sup>+sidereal equivalent of U.T.- $\lambda$

Otherwise add  $\Delta X = \Delta_{xy} \cos \theta$ ,  $\Delta Y = \Delta_{xy} \sin \theta$ ,  $\Delta Z$  to solar co-ordinates to eliminate parallax.

29 2200		300	400	500	600
14 6100		700	800	900	1000
0		1100	1200	1300	1400

This table gives the Julian Day numbers for January 0 of every leap year from A. D. 1100 to A. D. 1896, and the reductions to be applied to them to obtain the numbers for January 0 of the leap years in other centuries from 1697 B. C. to A. D. 2296, except in the 20th century which is tabulated on the following two pages.

## Gregorian Calendar

\* For Jan —1: these century years are not leap years.

\*For Jan. —1; these century years are not leap years.

In the following table, for dates from 1582 October 15 to 1583 December 31 inclusive, Gregorian calendar, *diminish all numbers by 10*.

In century years of the Gregorian calendar that are not leap years, for *January 0* use the number 1 instead of the tabular value 0, and for *February 0* use 32 instead of 31.

Latitude of observer is sum of corrected observed altitude of Polaris and (*a*<sub>0</sub>+*a*<sub>1</sub>+*a*<sub>2</sub>).  
Azimuth of Polaris is product of (*b*<sub>0</sub>+*b*<sub>1</sub>+*b*<sub>2</sub>) by secant of latitude.

$$\alpha_{\text{Date}} = \alpha_{1950} + f + g \sin (G + \alpha_{1950}) \tan \delta_{1950}$$

$$\delta_{\text{Date}} = \delta_{1950} + g \cos (G + \alpha_{1950})$$

In the formula for  $\alpha$ , the last term is to be expressed in seconds of time by multiplying  $g$  in minutes of arc by 4, where the factor 4 is applied by using the tabular value of  $4 \tan \delta$ .

DIFFERENTIAL ABERRATION

The correction for differential stellar aberration to be *added* to the observed differences  $\Delta\alpha$  and  $\Delta\delta$  of the right ascension and declination of an object relative to a comparison star, measured in the sense object *minus* star in units of 1<sup>m</sup> and 1' respectively, to obtain the true differences, is:

In right ascension,  $a\Delta\alpha + b\frac{\Delta\delta}{10}$  in units of 0.001,

In declination,  $c\Delta\alpha + d\frac{\Delta\delta}{10}$  in units of 0".01,

where *a*, *b*, *c*, *d*, are obtained from the table below with arguments *H*+ $\alpha$  and  $\delta$ , and may in general be taken out without interpolation; for the signs, see opposite page.

## DIFFERENTIAL ABERRATION

For positive declinations, take the signs of  $b$  and  $c$  (which are always opposite) from the top of the column when the argument  $H+\alpha$  is on the left, from the bottom when  $H+\alpha$  is on the right. For negative declinations, reverse the signs of  $b$  and  $c$ .

The signs of  $a$  and  $d$  (which are always alike) are independent of the sign of  $\delta$ , and also of whether  $H+\alpha$  is on the left or the right.

DIFFERENTIAL PRECESSION AND NUTATION, 1960

The correction for differential precession and nutation to be *added* to the observed differences  $\Delta\alpha$  and  $\Delta\delta$  of the right ascension and declination of an object relative to a comparison star, measured in the sense object *minus* star in units of 1<sup>m</sup> and 1' respectively, is:

In right ascension,  $e\Delta\alpha \frac{10 \tan \delta}{15} - f\Delta\delta \frac{10 \sec^2 \delta}{225}$ , units of 0<sup>.001</sup>;  
in declination,  $f\Delta\alpha$ , units of 0<sup>.01</sup>;

where *e* and *f* are taken from the table below, with the signs given in the table when 0<sup>h</sup> ≤  $\alpha$  ≤ 12<sup>h</sup>, but with the opposite signs when 12<sup>h</sup> ≤  $\alpha$  ≤ 24<sup>h</sup>.

NOTATION

Arg. Function		Differences				$f(t_p)=f(t_0+ph)=f_p$
		1st	2nd	3rd	4th	$\delta_p=f_{p+\frac{1}{2}}-f_{p-\frac{1}{2}} \quad \delta_p^2=\delta(\delta_p)$
$t_{-2}$	$f_{-2}$					$\delta_{\frac{1}{2}}=f_1-f_0 \quad \delta_0^2+\delta_1^2=\delta_{1\frac{1}{2}}-\delta_{-\frac{1}{2}}$
$t_{-1}$	$f_{-1}$	$\delta_{-1\frac{1}{2}}$	$\delta_{-1}^2$			$\delta_0^2=\delta_{\frac{1}{2}}-\delta_{-\frac{1}{2}}=f_1-2f_0+f_{-1}$
$t_0$	$f_0$	$\delta_{-\frac{1}{2}}$	$\delta_0^2$	$\delta_{\frac{1}{2}}^3$	$\delta_0^4$	$\delta_{\frac{1}{2}}^3=\delta_1^2-\delta_0^2=f_2-3f_1+3f_0-f_{-1}$
$t_1$	$f_1$	$\delta_{\frac{1}{2}}$	$\delta_1^2$			$\delta_0^4=\delta_{\frac{1}{2}}^3-\delta_{-\frac{1}{2}}^3=f_2-4f_1+6f_0-4f_{-1}+f_{-2}$
$t_2$	$f_2$	$\delta_{1\frac{1}{2}}$				

BESSEL'S INTERPOLATION FORMULA

$$f_p=f_0+p\delta_{\frac{1}{2}}+B_2(\delta_0^2+\delta_1^2)+B_3\delta_{\frac{1}{2}}^3+B_4(\delta_0^4+\delta_1^4)+\dots$$

The maximum truncation error of the interpolate  $f_p$  from neglecting each order of difference is less than 0.5 in the unit of the end figure of the tabular function if

$$\delta^2 < 4 \qquad \delta^3 < 60 \qquad \delta^4 < 20 \qquad \delta^5 < 500$$

If  $\delta^2$  is replaced by  $\delta_m^2=\delta^2-0.184 \delta^4$ , the corresponding limit for  $\delta^4$  is raised to 1000;  $\delta_{\frac{1}{2}}^3$  may be replaced by  $\delta_{m1}^2-\delta_{m0}^2$ .

PRECEPTS FOR USING THE TABLES

Table XIII. Round the interpolating factor  $p$  to 4 decimals; the required value of  $B_2$  is the tabular value opposite the interval in which  $p$  lies or, if  $p$  exactly equals a tabular argument, the value above and to the right of  $p$ . The effects of third and fourth differences can be estimated from the values of  $B_3$  and  $B_4$  in the last column.

Table XIV. The table is entered with the tabular arguments nearest the true values of  $p$  and  $\delta_0^2+\delta_1^2$ , to obtain directly the value of the second-difference correction; this correction always has the opposite sign to  $\delta_0^2+\delta_1^2$ .

Table XV. The value of  $B_2$  may be obtained by mental linear interpolation since the first difference of  $B_2$  is never greater than 4. The corrections for third and fourth differences, which are usually necessary when Table XIII cannot be used, are taken from the Tables XVI and XVII; these tables are similar to Table XIV, but include a guarding decimal, and require mental interpolation for some ranges of the argument, to reduce the error of the interpolate.

Errors. In addition to the truncation error, an interpolate is subject to errors from the following sources:

		Maximum error
$f_0+p\delta_{\frac{1}{2}}$	Rounding errors in $f_0, f_1$	0.5
$B_2(\delta_0^2+\delta_1^2)+B_3\delta_{\frac{1}{2}}^3+\dots$	Rounding errors in tabular values	0.2
$B_2(\delta_0^2+\delta_1^2)$	Rounding error of $B_2$ from Table XIII	0.00051( $\delta_0^2-\delta_1^2$ )
$B_2(\delta_0^2+\delta_1^2)$	Table XIV, using nearest arguments	0.7
$B_2(\delta_0^2+\delta_1^2)$	Error of $B_2$ from Table XV	0.00011( $\delta_0^2-\delta_1^2$ )
$B_3\delta_{\frac{1}{2}}^3+B_4(\delta_0^4+\delta_1^4)$	Tables XVI and XVII, with mental interpolation	0.3
$f_p$	Final rounding error	0.5

## EXAMPLES

To find (a) the right ascension of the Sun, and (b) the horizontal parallax of the Moon, at 16<sup>h</sup> 23<sup>m</sup> 15<sup>s</sup>.9 E. T., on 1960 January 4. The tabular values, and their differences in units of the end figure of the functions, are:

1960 Jan.	R.A. of Sun			$\delta$	$\delta^2$	H.P. of Moon		$\delta$	$\delta^2$	$\delta^3$	$\delta^4$
	<sup>h</sup>	<sup>m</sup>	<sup>s</sup>			'	"				
3.0	18	50	30.27	+26452	-36	4.0	57 08.023	-27214	+1211	+386	-83
4.0	18	54	54.79	+26413	-39	4.5	56 40.809	-25617	+1597	+303	-83
5.0	18	59	18.92	+26369	-44	5.0	56 15.192	-23717	+1900	+227	-76
6.0	19	03	42.61		-44	5.5	55 51.475		+2127		-69

(a) The tabular interval is one day; the interpolating factor  $p$  is therefore 0.68282. From Table XIII,  $B_2 = -0.054$ ; and

$$f_p = 18^h 54^m 54^s.79 + 0.68282(+264^s.13) - 0.054(-0^s.39 - 0^s.44) = 18^h 57^m 55^s.19$$

Alternatively, from Table XIV, with arguments  $p = 0.68$ ,  $\delta_0^2 + \delta_1^2 = 85$ , the second-difference correction  $B_2(\delta_0^2 + \delta_1^2) = 5$ ; and

$$f_p = 18^h 54^m 54^s.79 + 0.68282(+264^s.13) + 0^s.05 = 18^h 57^m 55^s.19$$

(b) The tabular interval is 0<sup>s</sup>.5; the interpolating factor  $p$  is therefore 0.36564. From Table XV,  $B_2 = -0.0580$ ; from Table XVI,  $B_3\delta_0^3 = 1.5$ , using  $p = 0.366$ ,  $\delta_0^3 = 300$ ; from Table XVII,  $B_4(\delta_0^4 + \delta_1^4) = 1.7$ , using  $p = 0.366$ ,  $\delta_0^4 + \delta_1^4 = 160$ ; and

$$f_p = 56' 40'' 809 + 0.36564(-25'' 617) - 0.0580(+1'' 597 + 1'' 900) + 0'' 0015 - 0'' 0017 = 56' 31'' 239$$

## EXPLANATION

The following description of the contents of this volume is limited to explaining the precise meanings of the tabular quantities, and specifying the basic tables used in the computations and the values adopted for the fundamental constants. A separate volume, *Explanatory Supplement*, contains a more detailed explanation of the ephemerides, and includes the formulae and auxiliary tables that are used in making the calculations.

Beginning with the volume for 1960, the tabular argument in the fundamental ephemerides of the Sun, Moon, and planets is Ephemeris Time; in nearly all of the other ephemerides, the argument is Universal Time. Ephemeris Time is the uniform measure of time defined by the laws of dynamics and determined in principle from the orbital motions of the planets, specifically the *orbital motion of the Earth* as represented by NEWCOMB'S *Tables of the Sun*. Universal Time is defined by the *rotational motion of the Earth*, and is determined from the apparent diurnal motions which reflect this rotation; because of variations in the rate of the rotation, Universal Time is not rigorously uniform.

Ephemeris Time is the independent variable in the gravitational theories of the Sun, Moon, and planets. The actual argument of ephemerides computed from these gravitational theories is necessarily Ephemeris Time defined by the laws of motion, instead of Universal Time defined by the variable rotation of the Earth; but in the volumes for years preceding 1960, the distinction was not formally recognized, and the arguments of the ephemerides were designated as Universal Time.

A gravitational ephemeris expresses the position of a celestial body as a function of Ephemeris Time; and, at any instant, the measure of Ephemeris Time is the value of the argument at which the ephemeris position is the same as the actual position at the instant. That is, the measure of time is determined by the inverse relation expressing the time as a function of the position, and this relation is the practical means of determining its numerical value. The Ephemeris Time at any instant is obtained from observation by directly comparing observed positions of the Sun, Moon, and planets with gravitational ephemerides of their coordinates; observations of the Moon are the most effective and expeditious for this purpose. An accurate determination, however, requires observations over a more or less extended period; in practice, it takes the form of determining the correction  $\Delta T$  that must be applied to Universal Time to obtain Ephemeris Time:

$$E.T. = U.T. + \Delta T.$$

The Universal Time at any instant may be obtained with little delay from observations of the diurnal motions.

The numerical measure in which Ephemeris Time is reckoned is defined by the apparent *annual motion of the Sun in longitude*. Universal Time, in principle, is determined by the *average rate of the apparent diurnal motion of the Sun relative to the meridian of Greenwich*; but in practice, the numerical measure of Universal Time at any instant is formally computed from its relation to the measure of time defined by the diurnal motion of the vernal equinox (First Point of Aries), which is known as *sidereal time* and which may be rapidly and accurately determined from observations of the diurnal motions of stars.

Universal Time is a particular case of the measure known in general as *mean solar time*. A reckoning of time which conforms more or less closely to the recurrence of daylight and darkness determined by the diurnal motion of the Sun, and which is quickly obtainable with high precision from observation, is a practical necessity; but because of the variations in the rate of motion in hour angle due to the inequalities in the annual motion of the Sun along the ecliptic and to the inclination of the ecliptic to the equator, the measure of time that is directly defined by the actual diurnal motion of the Sun, known as *apparent solar time*, is impracticable for the purpose of precise timekeeping. Instead, mean solar time is introduced, defined by the apparent diurnal motion of a conventional fiducial point located on the mean celestial equator of date, and characterized by a uniform sidereal motion along the equator at a rate which is virtually equal to the mean rate of the annual motion of the Sun along the ecliptic; relative to any meridian of longitude, this point has a diurnal motion in hour angle virtually the same as the average diurnal motion of the Sun, and uniform except for variations of the local meridian and variations of the rate of rotation of the Earth.

The position of this moving point is abstractly defined by a conventional formula for its right ascension; the practice in the past has been to adopt for the right ascension an expression as nearly identical with the expression for the mean longitude of the Sun on the ecliptic as is possible, consistent with a sidereal motion at a constant rate. The position in right ascension differs from the mean longitude of the Sun by only a slight, progressively increasing, excess of  $0.0203 T^2$  due to the secular acceleration of the Sun, where  $T$  is the number of centuries after 1900. The position in hour angle is never more than about  $16^m$  from the Sun. This abstract fiducial point, formally defined by the conventional expression for its right ascension, has therefore traditionally been known as the fictitious mean sun.

Unlike the diurnal motion of the actual Sun which defines apparent solar time, the diurnal motion of the fictitious mean sun which defines mean solar time cannot be actually observed, since this fiducial point has no physical counterpart; but the expression for its right ascension fixes its position among the stars at every instant, and is a means of determining its diurnal motion from the observable diurnal motions of the stars, and conventionally defining an exact measure of mean solar time by expressing the definition in the form of a relation to sidereal time. The sidereal time defined by the diurnal motion of the vernal equinox is measured by the hour angle of the equinox, which represents the position of the equinox in its diurnal circuit; its value at any instant is determined by observing meridian transits of stars.

From the formula for the right ascension of the fictitious mean sun, the numerical expression is obtained that formally defines the conventional measure of mean solar time by prescribing its relation to the sidereal time measured by the hour angle of the equinox. In practice, the hour angles of the equinox that determine the instants of successive mean midnights are calculated from this relation; and with them, the mean solar time at any instant is calculated from the observed hour angle of the equinox at this instant. The ephemeris of *Universal and Sidereal Times* on pages 10–17, containing the calculated sidereal time at 0<sup>h</sup> U.T., is for this purpose. Universal Time is the mean solar time on the Greenwich meridian, reckoned in days of 24 mean solar hours beginning with 0<sup>h</sup> at midnight; and the tabular sidereal times at 0<sup>h</sup> U.T. are the Greenwich hour angles of the vernal equinox that conventionally *define* the instants of successive Greenwich mean midnights.

The period of one diurnal circuit of the equinox in hour angle, between two consecutive upper meridian transits, is a sidereal day; it is divided into 24 sidereal hours, reckoned from 0<sup>h</sup> at upper transit which is known as sidereal noon. The *true* equinox is at the intersection of the true equator of date with the ecliptic of date; the time measured by its diurnal motion is *apparent sidereal time*. The position of the true equinox is affected by the nutation of the axis of rotation of the Earth; and the nutation consequently introduces irregular periodic inequalities into the apparent sidereal time and the length of the sidereal day. The time measured by the diurnal motion of the *mean* equinox of date, which is affected by only the secular inequalities due to the precession of the axis, is *mean sidereal time*. Apparent sidereal time minus mean sidereal time is the *equation of the equinoxes* due to the nutation; in the volumes immediately preceding 1960, it was designated as the nutation in right ascension, and was included in the ephemeris of the Sun.

The tabular values of the Greenwich mean sidereal time at 0<sup>h</sup> Universal Time on successive dates are computed from NEWCOMB's expression,

$$6^{\text{h}} 38^{\text{m}} 45^{\text{s}}.836 + 86\ 40184^{\text{s}}.542\ T + 0^{\text{s}}.0929\ T^2,$$

where, for any date,  $T$  denotes the number of Julian centuries of 36525 days which, at midnight of the beginning of the day, have elapsed since noon on 1900 January 0 at the Greenwich meridian. The apparent sidereal time is obtained by adding the equation of the equinoxes to the mean sidereal time.

The instant that is designated as 0<sup>h</sup> U.T. each day is the instant at which the vernal equinox during its apparent diurnal motion reaches a Greenwich hour angle equal to the value calculated from this formula with the numerical value of  $T$  that represents the integral number of days from the epoch to date. At the instant of any observed Greenwich sidereal time, the interval which has elapsed since 0<sup>h</sup> U.T., expressed in sidereal units, is immediately obtained by subtracting the tabular sidereal time at 0<sup>h</sup> U.T. from the observed sidereal time at the instant; and the Universal Time at the instant is the equivalent measure of this interval in units of mean solar time.

The mean solar day, of 24 mean solar hours, is the interval of time between the two instants at which the equinox reaches the tabular hour angles for two

consecutive dates, corrected for the variations of the meridian due to the motion of the geographic poles and to variations of the vertical. Because of the dependence of the diurnal motion on the rate of rotation of the Earth, the variations of the rotation cause inequalities in the mean solar time as determined from these tabular hour angles of the equinox, and the mean solar day is not invariable in length; but the ratio of the sidereal and mean solar measures of time is not changed by variations of the rotation of the Earth, since the two measures are affected proportionally. The ratio of the mean solar day to the mean sidereal day is 1.00273 79093; and the equivalent measures of the length of the day are:

Mean sidereal day . . . 23<sup>h</sup> 56<sup>m</sup> 04<sup>s</sup>.09054 of mean solar time  
 Mean solar day . . . . . 24<sup>h</sup> 03<sup>m</sup> 56<sup>s</sup>.55536 of mean sidereal time

From these equivalents, Tables VIII and IX have been constructed for converting intervals of time from one measure to the other. To the order of accuracy of 0<sup>s</sup>.01, these tables may be used for either mean or apparent sidereal time; but in more precise calculations, separate account must be taken of the equation of the equinoxes. The measure of an interval expressed in hours, minutes, and seconds may be converted to the equivalent fraction of a day by Table X.

The expression for the value of the hour angle of the equinox which defines 0<sup>h</sup> U.T. is obtained by adding 12<sup>h</sup> to NEWCOMB's expression for the right ascension of the fictitious mean sun, originally in order that mean midnight would be the instant of lower meridian transit of the fictitious mean sun, and the measure of mean solar time at any other instant, reckoned from midnight, would be the hour angle of the fictitious mean sun increased by 12<sup>h</sup>. Accordingly, prior to 1960, the additional designation "Right Ascension of Mean Sun + 12<sup>h</sup>" was sometimes given to the sidereal time at 0<sup>h</sup> U.T. However, because of the variations in the rate of rotation of the Earth, the measure actually obtained by the established practical method of determining Universal Time does not rigorously conform to this traditional geometric interpretation.

In actual practice, the tabular values of the hour angle of the equinox at successive intervals of a mean solar day are formally calculated from successive values of  $T$  at the *numerically uniform* interval 1/36525. Numerically, therefore, the tabular values are at equal intervals of the sidereal motion of the fictitious mean sun in right ascension, since NEWCOMB's expression, *by construction*, represents a strictly uniform sidereal motion with respect to  $T$ . However, the instants at which the equinox reaches the tabular hour angles in its diurnal motion depend on the variable rotation of the Earth, and are at slightly unequal intervals of time; during these successive intervals the actual amounts of the uniform sidereal motion of the mean sun are unequal. The right ascension of the mean sun is independent of the rotation of the Earth; but the diurnal motion of the equinox in hour angle is determined by the rotation of the Earth and by the sidereal motion of the equinox due to precession. The sidereal motion of the equinox is independent of the rotation, and affects the hour angle of the equinox and the right ascension of the mean sun alike; but in the motion that is due to the rotation of the Earth, the equinox requires

a varying interval of time to describe the tabular interval of hour angle between consecutive midnights, including the constant tabular amount due to the sidereal motion of the mean sun. Consequently, the hour angle of the equinox, and the actual right ascension of the mean sun increased by  $12^h$ , do not both reach the tabular value of the sidereal time of  $0^h$  U.T. at identically the same instant.

The tabular value is the hour angle which the *equinox* reaches at mean midnight *by definition*, but is not precisely equal numerically to the right ascension of the mean sun increased by  $12^h$  at this instant; this former designation is inexact when the variation of mean solar time from a uniform measure is recognized, and was therefore eliminated from the ephemeris when a formal distinction was made between Universal Time and Ephemeris Time. At this hour angle of the equinox the fictitious mean sun is not exactly on the lower meridian. The instant of  $0^h$  U.T. is precisely defined, not by the meridian transit of the mean sun, but abstractly by the numerical expression from which the tabular sidereal times at  $0^h$  U.T. are computed; and the traditional descriptive definition of mean solar time as the hour angle of the mean sun increased by  $12^h$  is not an exact equivalent of the actual conventional measure.

The operational procedure used in practice for determining the Universal Time at any instant constitutes the actual definition, and supersedes the geometric interpretation that originally motivated this procedure before variations in the rotation of the Earth had been recognized. Universal Time as obtained in accordance with the established practical method, from the observed sidereal time at the instant and the tabular sidereal time at  $0^h$  U.T., is essentially a formal measure defined by the abstract numerical expression conventionally adopted for prescribing the value of the hour angle of the vernal equinox that determines the instant designated as  $0^h$  U.T.; and it is distinguished by being strictly in accordance with the measure of time defined by the rotation of the Earth. The formal measure of mean solar time is equivalent to the measure of time defined by the diurnal motion of the fictitious mean sun; but the actual *numerical value*, as obtained in practice from the diurnal motion of the equinox and the right ascension of the mean sun, is not the exact equivalent of the traditional *geometric representation* of this measure.

Likewise, the mean solar day is not exactly the period of one diurnal circuit of the fictitious mean sun in hour angle, as it would be were there no variations in the rate of rotation. The actual amount of the motion of the mean sun in right ascension during the interval of time between consecutive Greenwich mean midnights is not invariably the same as the constant amount with which the tabular hour angles of the equinox that determine the instants of midnight are formally calculated. At the instants of  $0^h$  U.T., the mean sun is at varying hour angles, depending on the accumulated variations of the amounts of its sidereal motion during successive mean solar days.

The mean solar day, when determined from observations of stars, and corrected for the variations of the meridian, is rigorously proportional to the period of rotation of the Earth; but the rate of motion of the mean sun in hour angle is in a slightly varying ratio to the rate of rotation of the Earth, and the hour angle increased by  $12^h$  is not an exact measure of mean solar time. Strictly, in

the expression for the right ascension of the mean sun,  $T$  denotes Ephemeris Time; and therefore  $0^h$  U.T. is the instant at which the equinox reaches an hour angle numerically equal to the value which the right ascension of the mean sun increased by  $12^h$  has already reached at an instant  $\Delta T$  earlier. The lower meridian transit of the mean sun occurs at U.T.= $0.00274 \Delta T$ , when E.T.= $1.00274 \Delta T$ .

The observation of meridian transits of stars is the only practicable means of making, with the necessary rapidity and precision, the daily determinations of time by observation that are essential for practical purposes; and Universal Time is therefore an indispensable standard. Moreover, it is important as a means of determining the variations in the rotation of the Earth; and it is nearly enough uniform for most practical purposes. Ephemeris Time has been adopted as the standard for precise timekeeping, for physical measurements of high precision, and for accurate astronomical computations and theoretical investigations; but Universal Time is the basis of civil timekeeping, and is the standard in astronomical observation and in the practical applications of astronomy. In ephemerides intended only for facilitating astronomical observations, or for navigation or surveying, the argument is Universal Time.

In practice, in determining time, the inequalities that are due to variations of the vertical may be neglected, as they are too small in comparison with errors of observation to be significant except in an analysis of a long series of observations; but because of the high accuracy that has been reached in timekeeping, the inequalities due to the polar motion and to the annual variation in the rate of rotation of the Earth have become of practical importance. Beginning with 1956, in accordance with resolutions of the International Astronomical Union, determinations of Universal Time have been corrected for the annual variation in the rate of rotation, and for the variation in the position of the meridian due to the motion of the geographic poles.

Previous to 1925, mean solar time was reckoned from noon in astronomical practice. The mean solar day beginning at noon, 12 hours *after* the midnight at the beginning of the same civil date, was known as the *Astronomical Day*. Mean solar time reckoned from mean noon on the meridian of Greenwich was designated *Greenwich Mean Time*; reckoned from mean noon on a local meridian, *local mean time*. Beginning with the volumes for 1925, Universal Time was introduced in the national ephemerides under various names, a discontinuity of 12 hours being made in the arguments, so that December 31.5 in the volumes for 1924 designated the same instant as January 1.0 in the volumes for 1925. In the *British Nautical Almanac* the designation *Greenwich Mean Time* was still used for the new reckoning, together with *local mean time* where appropriate, whereas in the *American Ephemeris and Nautical Almanac* the designation *Greenwich Civil Time* was adopted, together with *local civil time*. This confusion in terminology was finally removed by dropping both designations and substituting Universal Time; it is, however, now called *Greenwich Mean Time* in the navigational publications of English-speaking countries. Care is necessary to avoid confusion; to distinguish the two reckonings that have both been called *Greenwich Mean Time*, the desig-

nation Greenwich Mean Astronomical Time should be used in referring to dates before 1925 when the time then known as Greenwich Mean Time is intended, and for dates in and after 1925 the reckoning from midnight should be exclusively used.

In the ephemerides, the hours of the mean solar day are counted from 0 to 24. As ordinarily used in civil life, they are counted from 0 to 12 in two series; the first series, designated A. M., extends from midnight to noon, and the second, designated P. M., from noon to midnight.

On any particular meridian of longitude, the local time, either solar or sidereal, is more advanced than at the same instant on any meridian farther west, and less advanced than on any meridian farther east; the difference amounts to one hour for each  $15^\circ$  difference in longitude. For civil purposes, however, clocks are customarily regulated to the same time throughout an entire zone of longitude about  $15^\circ$  wide; in particular, the United States is divided into four time zones, and the clock time kept throughout each zone is the local mean solar time of a selected standard meridian near the middle of the zone. Time in this system is known as Standard Time. The Standard Time throughout the British Isles is Universal Time. It is now common practice in many localities to advance the clock time during part of the year; this advanced time is known in the United States as Daylight Saving Time, and in the United Kingdom as Summer Time.

The extension of the system of Standard Time completely over the Earth is known as Zone Time. The standard meridians of the international time zones are  $15^\circ$  apart, beginning with the Greenwich meridian; and each zone is designated by the number of hours to be added algebraically to the Zone Time in order to obtain Universal Time. For example the Eastern Standard Time zone is Zone  $+5^h$ . Zone  $+12^h$  and Zone  $-12^h$  each extends only to the International Date Line, which is everywhere along or near the 180th meridian; when the Date Line is crossed from east to west, the time is advanced by exactly 24 hours, i. e., the date abruptly increases by one day, with an additional change at places where the Date Line coincides with a time zone boundary.

### **Calendar** (*pages 1-3*)

Over extended intervals, civil time is ordinarily reckoned according to conventional calendar years and adopted historical eras; in constructing and regulating civil calendars, and fixing ecclesiastical calendars, a number of auxiliary cycles and periods are used. The principal chronological eras and cycles are listed on page 1; and the Gregorian calendar for the current year is given on pages 2-3.

To facilitate chronological reckoning for many purposes, the astronomical days, beginning at Greenwich noon, are numbered consecutively, from an epoch sufficiently far in the past to precede the historical period; the number which denotes a day in this continuous count is the Julian Day Number. The Julian Day reckoning begins with Julian Day Number 0 for January 1, 4713 B.C., Julian proleptic calendar; the Julian Day Number therefore denotes the length of time that has elapsed, at Greenwich noon at the beginning of the

astronomical day, since this epoch. The Julian Day Numbers for the current year are given in the calendar on pages 2-3; from Table I they may be found for other years up to A.D. 2300, and it is readily apparent how this table may be extended over any interval.

Dates expressed in Julian Days and fractions of a day represent time elapsed at the instant. In several of the ephemerides in this volume, the arguments are designated by the Julian Dates in addition to the Gregorian calendar dates. On pages where the argument is Ephemeris Time, the Julian Date, like the calendar date, refers to ephemeris days; but the Julian Day begins at 12<sup>h</sup> E.T., the calendar day at 0<sup>h</sup> E.T. The terminology *Julian Ephemeris Date* may be used to distinguish the Julian Date with the day beginning at 12<sup>h</sup> E.T. instead of at 12<sup>h</sup> U.T. (Greenwich Mean Noon), where it is essential to avoid ambiguity, as in dating orbital elements, or in formulae for light curves of variable stars, where the time must be given to a large number of decimals of a day.

The period of one complete circuit of the fictitious mean sun in right ascension, beginning at the instant when the right ascension is 18<sup>h</sup> 40<sup>m</sup>, is known as the Besselian solar year, and is an advantageous unit of time for some astronomical purposes. In 1960, the beginning of the Besselian year is January 1<sup>st</sup> 1945 Ephemeris Time; this instant is denoted by the notation 1960.0, and is given at the foot of each page of the calendar. Because of the secular excess of the right ascension of the fictitious mean sun over the mean longitude of the Sun, the Besselian year is shorter than the tropical year by the amount 0<sup>h</sup> 148 *T*, where *T* denotes the time in centuries after 1900.

### Phenomena (pages 4-9)

The principal configurations of the Sun, Moon, and planets with one another during the year, and other phenomena of general interest, are listed on these pages.

The *Diary* on pages 5-7 contains, in chronological order with times to the nearest hour: the geocentric phenomena for which only the dates are given on page 4; the occultations of the four bright stars *Aldebaran*, *Regulus*, *Spica*, and *Antares*, and of the planets visible to the unaided eye, for which at the top of page 5 another table is given that includes the area of visibility, the tabular times being for geocentric conjunction in right ascension; and the dates of the eclipses and transits that occur during the year, for which the areas of visibility are indicated at the bottom of page 4. In addition, the *Diary* includes the phases of the Moon, and apogee and perigee of the Moon; the closest approach of Mars to the Earth, when the geocentric distance passes through a minimum; geocentric conjunctions in apparent right ascension of the planets with the Moon, with one another, and with the bright stars *Aldebaran*, *Regulus*, *Spica*, and *Antares*, except when these phenomena occur within 24 hours of New Moon or within 10° of the Sun; and the geocentric phenomena of Ceres, Pallas, Juno, and Vesta, for which the dates alone are given at the bottom of page 8. The magnitudes and elongations from the Sun on every fifth day for

the inferior planets and every tenth day for the superior planets, and approximate magnitudes of the minor planets Ceres, Pallas, Juno, and Vesta at 40-day intervals, are tabulated on pages 8-9.

The geocentric phenomena differ from the actually observed configurations by the effects of the geocentric parallax at the place of observation, which for configurations with the Moon may be quite large. The tabular times for the stationary points of the planets are the instants at which the planet is stationary in *apparent* geocentric right ascension; but for the configurations of the planets with the Sun, the tabular times are for the *geometric* configurations. The times of conjunction and opposition are, respectively, the instants when the geocentric longitude of the planet differs by  $0^\circ$  and  $180^\circ$  from the geocentric longitude of the Sun. From inferior conjunction to superior conjunction of Mercury or Venus, or from conjunction to opposition of a superior planet, the elongation from the Sun is west; from superior to inferior conjunction, or from opposition to conjunction, the elongation is east. Because of the difference in latitude, the elongations do not in general pass through  $0^\circ$  or  $180^\circ$  as they change from west to east or from east to west. The tabular times of the greatest elongations of Mercury and Venus are the instants when the true geocentric angular distance from the Sun is a maximum.

The times of the equinoxes and solstices, which on page 4 are given to the nearest minute of Universal Time, are the instants when the apparent longitude of the Sun is a multiple of  $90^\circ$ .

The times given for the greatest brilliancy of Venus are the instants at which the value of the expression

$$\frac{(r + \Delta - R)(r + \Delta + R)}{r^3 \Delta^3}$$

is a maximum, where  $r$  and  $R$  denote, respectively, the heliocentric distances of Venus and the Earth, and  $\Delta$  is the geocentric distance of Venus.

The heliocentric phenomena for which dates are given on page 4 are the perihelion and aphelion, the passages through the nodes on the ecliptic, and the greatest north and south heliocentric latitudes, in the actual disturbed motion. Because of perturbations, the dates are not in general the same as the dates that would be obtained from the elements of the mean orbit; the date on which the radius vector is a minimum may differ considerably from the date on which the heliocentric longitude of the planet is equal to the longitude of the perihelion of the mean orbit, and similarly the heliocentric longitude of the planet when its heliocentric latitude becomes zero may differ from the longitude of the mean node. At the ascending node, the planet passes through the plane of the ecliptic from south to north, and the heliocentric latitude vanishes in changing from negative to positive; at the descending node, the latitude changes from positive to negative as the planet passes through the plane of the ecliptic from north to south.

### Universal and Sidereal Times (*pages 10-17*)

The sidereal time (Hour Angle of First Point of Aries) at 0<sup>h</sup> Universal Time, and the Universal Time at 0<sup>h</sup> sidereal time (Transit of First Point of Aries), which formerly were included in the ephemeris of the Sun, are tabulated both for the mean equinox of date, and for the true equinox with the short-period terms of nutation included. The definition of Universal Time was not changed when Ephemeris Time was formally introduced into astronomical practice. The practical method of determining Universal Time that was in established use before 1960 was retained; and the numerical reckoning of Universal Time was continued without discontinuity except for increased precision arising from the use of improved values of the nutation.

In the ephemeris of sidereal time at 0<sup>h</sup> U.T., the argument is the calendar date and the equivalent Julian Date. In the ephemeris of Universal Time at 0<sup>h</sup> sidereal time on each day, the argument is the Greenwich Sidereal Date, defined as the number of sidereal days, determined by the equinox of date, that have elapsed at Greenwich since the beginning of the sidereal day which was in progress at J.D. 0.0. The integral part of the Greenwich Sidereal Date is called the Greenwich Sidereal Day Number; it is a means of consecutively numbering the successive sidereal days beginning at the *transits* of the First Point of Aries, similar to the Julian Day reckoning of the successive mean solar days beginning at the instants of the *tabular hour angles* of the First Point of Aries. The Greenwich Sidereal Day is the number of sidereal days that have elapsed at 0<sup>h</sup> Greenwich sidereal time since the Greenwich sidereal 0<sup>h</sup> that immediately preceded J.D. 0.0; the zero day is the sidereal day that was in progress at the beginning of the Julian Era.

From these ephemerides for the meridian of Greenwich, the local mean time on any meridian of longitude may be calculated from the local sidereal time, or conversely. For this purpose, the longitude is expressed in time. The measure of longitude in arc may be converted to the equivalent measure in time by Table XII; the reverse transformation is obtained by Table XI.

The longitude expressed in time and reckoned positive westward is numerically the amount by which Universal Time is greater than the local mean solar time at the same instant. At the instant when the local mean time is 0<sup>h</sup>, the longitude is therefore the measure of the interval of mean solar time that has elapsed at Greenwich since 0<sup>h</sup> U.T.; and adding the equivalent measure of this mean solar interval in units of sidereal time to the Greenwich sidereal time at 0<sup>h</sup> U.T. gives the sidereal time at Greenwich at the instant when the mean solar time on the *local* meridian is 0<sup>h</sup>. Like the mean solar times, the Greenwich sidereal time is greater than the local sidereal time at the *same* instant by the amount of the longitude; and therefore the *local* sidereal time at 0<sup>h</sup> local mean solar time is obtained directly by adding to the tabular Greenwich sidereal time at the *previous* instant of 0<sup>h</sup> U.T. the same *correction* as required to convert the mean solar interval measured by the longitude into an equivalent sidereal interval. This reduction may either be taken from Table IX, or obtained by means of the hourly variation +9<sup>s</sup>8565.

Similarly, the Universal Time of Greenwich sidereal 0<sup>h</sup> may be reduced to the local mean solar time of 0<sup>h</sup> local sidereal time at any longitude by applying the correction from Table VIII, or by means of the hourly variation  $-9^{\text{s}}8296$ .

*Conversion of sidereal time to mean solar time*

On 1960 July 7, at approximately 4<sup>h</sup> local mean solar time, in longitude 85° 15' west (+ 5<sup>h</sup> 41<sup>m</sup>), the observed apparent sidereal time is 23<sup>h</sup> 04<sup>m</sup> 56<sup>s</sup>.569. The Universal Time at this instant is approximately 10<sup>h</sup>; the equation of the equinoxes is therefore  $-0^{\text{s}}175$ , and subtracting this amount from the observed sidereal time gives the local mean sidereal time.

	h	m	s
Greenwich mean sidereal time, 0 <sup>h</sup> U.T., July 7 . . . .	18	59	50.725
Reduction for longitude (Table IX). . . . .			+ 56.018
Mean sidereal time, 0 <sup>h</sup> local mean solar time. . . . .	19	00	46.743
Local mean sidereal time at observation. . . . .	23	04	56.744
Sidereal interval since 0 <sup>h</sup> local mean solar time. . . .	4	04	10.001
Reduction to mean solar interval (Table VIII). . . .			- 40.001
Local mean solar time. . . . .	4	03	30.000

If the sidereal interval is less than 3<sup>m</sup> 56<sup>s</sup>.5, there are two mean solar times corresponding to the sidereal time, one a few minutes after the preceding 0<sup>h</sup>, and the other a few minutes before the following 0<sup>h</sup>, at a mean solar time interval of about 23<sup>h</sup> 56<sup>m</sup> 04<sup>s</sup>. The approximate mean solar time always determines which one is to be taken. Any local sidereal time within an interval of less than 3<sup>m</sup> 56<sup>s</sup>.5 after 0<sup>h</sup> local mean solar time will occur a second time on the same mean solar day; the subtraction of the local sidereal time of 0<sup>h</sup> from either of these two sidereal times will give the same numerical result, but the actual interval for the second value is 24 sidereal hours greater.

The conversion of sidereal time to mean solar time may also be made by adding to the mean solar time of the *preceding* local sidereal 0<sup>h</sup> the equivalent of the sidereal time in units of mean solar time.

*Conversion of mean solar time to sidereal time*

To convert mean solar time to mean sidereal time, add to the local mean sidereal time at 0<sup>h</sup> the equivalent measure of the local mean solar time in sidereal units. To obtain the apparent sidereal time, add further the equation of the equinoxes, interpolated to the time. As an example, on 1960 July 7, in longitude 85° 15' west (+ 5<sup>h</sup> 41<sup>m</sup>), at 4<sup>h</sup> 03<sup>m</sup> 30<sup>s</sup> local mean solar time, to determine the local sidereal time:

### Sun, Moon, and Planets

In addition to providing the fundamental ephemerides for the preparation of navigational almanacs and other derived ephemerides, one of the principal purposes of this section is for the exact comparison of theory with observation, for the immediate purpose of more accurately determining astronomical constants and establishing the location of the equinox and equator among the stars, in order eventually to improve astronomical theories and tables. Except where otherwise stated, the tabular positions are *apparent* positions, i. e., the positions in which the Sun, Moon, and planets would actually be seen from the center of the Earth at the tabular times, displaced by planetary aberration and referred to the coordinate systems determined by the instantaneous equator, ecliptic, and equinox, with Ephemeris Time as the argument; the value used for the light-time at unit distance is  $498^{\text{s}}38$ , corresponding to the adopted constant of aberration. For comparison with photographic observations, *astrometric* positions are given for Pluto and the minor planets; for the latter they are included with the apparent positions. Ephemerides that are intended for theoretical purposes, where a fixed reference system is needed, are referred to the *fixed equinox* of a convenient epoch; and Tables III and IV are for facilitating reductions from one equinox to another.

The tabular quantities at instants other than the tabular times may be obtained by interpolation with the requisite order of differences. For this purpose, differences are included in many of the ephemerides; and formulae and tables for interpolation are given on pages 476–481.

The ephemerides are computed strictly from the tables to which references are made, and with the standard values that are stated for the fundamental constants. No corrections are applied to bring the tables into better accord with later observations; and in accordance with the resolutions of the International Astronomical Union, no change has been made in the conventionally adopted value of any fundamental constant that was used in the volumes immediately preceding 1960.

The adoption of Ephemeris Time does not require any change in previous procedures for computing the ephemerides; the tabular values are unaltered, but the terminology is revised in order that the tabular argument may be correctly designated as Ephemeris Time instead of Universal Time. The tabular coordinates for 1960 January 1 in the ephemerides of the Sun and the inner planets are therefore the same as for 1959 December 32 in the immediately preceding volume, except for the small differences due to improved values of the nutation and to the inclusion of short-period terms of nutation; but in the ephemerides of the outer planets and the Moon, the coordinates are not computed from the same tables as before 1960. Only the calculation of meridian transits, and the computation of transit ephemerides and of phenomena that depend upon hour angles, are affected by the formal recognition of Ephemeris Time; the precepts used before 1960 led actually to slightly inexact results.

Ephemeris Time is not adapted to the calculation of hour angles, since the value of  $\Delta T$  is required for the determination of quantities that depend upon the rotation of the Earth. For facilitating practical calculations of

phenomena that depend upon hour angle and geographic location, an auxiliary reference meridian has therefore been introduced, known as the *ephemeris meridian*; it is defined as the meridian that is  $1.002738\Delta T$  east of the actual geographic meridian of Greenwich on the surface of the Earth; its position *in space* is where the Greenwich meridian would be if the Earth had rotated uniformly. Longitude reckoned from the ephemeris meridian is distinguished by the term *ephemeris longitude*. Beginning with 1960, the time given in previous volumes for meridian transit at Greenwich is designated by the term *ephemeris transit*, which is the Ephemeris Time of transit across the ephemeris meridian. Interpolation to other meridians by using the *ephemeris longitude* as the interpolating factor gives the Ephemeris Time of local meridian transit; in forming first differences of the tabular ephemeris transits for this purpose, it must not be overlooked that the *day* is part of each tabular time.

When referred to the ephemeris meridian, phenomena depending on the rotation of the Earth may be calculated in terms of Ephemeris Time by methods formally the same as the procedures by which calculations referred to the Greenwich meridian are made in terms of Universal Time. The hour angle and the meridian transit of the vernal equinox, which determine the tabular sidereal time at 0<sup>h</sup> Universal Time and the Universal Time at 0<sup>h</sup> sidereal time, are referred to the actual *geographic* meridian of Greenwich. The numerical value formally obtained from the *same numerical relation* as used to compute the sidereal time at 0<sup>h</sup> Universal Time, but with  $T$  reckoned expressly in Ephemeris Time, is the hour angle of the equinox referred to the *ephemeris meridian* at 0<sup>h</sup> Ephemeris Time, and is called *ephemeris sidereal time*. Numerically, therefore, the tabular values of sidereal time at 0<sup>h</sup> Universal Time are equally the values of ephemeris sidereal time at 0<sup>h</sup> Ephemeris Time. Ephemeris transit occurs at the instant when the ephemeris sidereal time is equal to the right ascension.

Until  $\Delta T$  is known, local hour angles referred to a *geographic* meridian cannot be calculated, but the ephemeris longitude where the actual local hour angle has any particular value may be determined entirely in terms of Ephemeris Time; and beginning with 1960, this procedure is followed in predictions of the general circumstances of eclipses. As soon as  $\Delta T$  becomes known, the longitudes may be referred to the Greenwich meridian, and the Universal Times when the hour angle has the given values at these geographic longitudes may be determined.

For the computation of ephemerides with Universal Time as the argument, the value of  $\Delta T$  is specifically required. Since  $\Delta T$  depends primarily upon the *irregular* variations in the rate of rotation of the Earth, it cannot be determined in advance with certainty and exactness, or incorporated in the tables, but must be separately applied as determined from time to time by actual observation. Since ephemerides must be computed several years in advance, those that have the argument Universal Time are necessarily based upon an extrapolated value of  $\Delta T$ . However, the uncertainty of the extrapolation, over the relatively short intervals necessary, is within the order of accuracy to which these ephemerides are calculated; in practice, to the degree of precision needed,

the ephemerides are for the most part unchanged by a transformation of the argument from Ephemeris Time to Universal Time.

Values of  $\Delta T$  as determined from discussions of observations are tabulated on page viii, together with estimated values for several later years.

The method of converting an ephemeris from Ephemeris Time to Universal Time depends upon whether hour angles are involved in the computation of the tabular quantities. When the tabular values are independent of the rotation of the Earth, an ephemeris for 0<sup>h</sup> Ephemeris Time may be converted to an ephemeris for 0<sup>h</sup> Universal Time by interpolating the tabular values to an interval  $\Delta T$  after 0<sup>h</sup> Ephemeris Time; if second differences are negligible, the interpolated values are obtained by adding algebraically to each of the tabular values for 0<sup>h</sup> Ephemeris Time the correction  $\frac{\Delta T}{h} \delta_{1/2}$ , where  $h$  is the tabular interval and  $\delta_{1/2}$  denotes the first difference.

The Universal Time of transit of the Moon or a planet across the meridian of Greenwich may be found by subtracting  $\Delta T$  from the Ephemeris Time of Greenwich transit that is obtained by interpolating the ephemeris transit from the geographic longitude of the ephemeris meridian, 1.002738  $\Delta T$  east, to longitude 0°. The ephemeris transit is the time on the Greenwich meridian at the instant of transit across the ephemeris meridian; the Greenwich transit follows ephemeris transit at an interval which to a first approximation exceeds  $\Delta T$  by the time equivalent of the motion in right ascension during the interval  $\Delta T$ . The Universal Time of Greenwich transit is therefore algebraically greater than the tabular ephemeris transit by approximately the amount  $\frac{\Delta T}{h} \delta_{1/2} \alpha$ .

The Greenwich transit of the Sun is determined from the equation of time which is tabulated in the ephemeris of the Sun; the calculation is given in the explanation of the equation of time.

### *Fundamental Units and Astronomical Constants*

#### *Time, Mass, and Length*

The fundamental epoch from which Ephemeris Time is reckoned is the epoch that NEWCOMB designated as 1900 January 0, Greenwich Mean Noon, but which actually is 1900 January 0<sup>d</sup> 12<sup>h</sup> E.T.; the instant to which this designation is assigned is the instant near the beginning of the calendar year A. D. 1900 when the geometric mean longitude of the Sun referred to the mean equinox of date was 279° 41' 48".04. Ephemeris Time is the measure of time in which NEWCOMB's *Tables of the Sun* agree with observation.

The primary unit of Ephemeris Time is the tropical year, defined by the mean motion of the Sun in longitude at the epoch 1900 January 0<sup>d</sup> 12<sup>h</sup> E.T.; its length in ephemeris days is determined by the coefficient of  $T$  in NEWCOMB's expression for the geometric mean longitude of the Sun,  $L$ , referred to the mean equinox of date, given among the elements of the Sun. The *ephemeris second* is defined as 1/31556925.9747 of the tropical year for 1900 January 0<sup>d</sup> 12<sup>h</sup> E.T.; it has been formally adopted as the fundamental invariable unit of time by the Comité International des Poids et Mesures. The ephemeris day is 86400

ephemeris seconds. The former fundamental unit of time was the mean solar second, defined as  $1/86400$  of the mean solar day.

In the astronomical system of measures, the usual unit of time is the ephemeris day. The fundamental unit of mass is the mass of the Sun. The unit of length is the astronomical unit, defined as the unit of distance in terms of which, in KEPLER's Third Law  $n^2 a^3 = k^2 (1 + m)$ , the semimajor axis  $a$  of an elliptic orbit must be expressed in order that the numerical value of the Gaussian constant  $k$  may be exactly 0.01720209895 when the unit of time is the ephemeris day (*Trans. Int. Astr. Union*, vol. VI, 1939, pages 20, 336, 357); in astronomical units, the mean distance of the Earth from the Sun, calculated by KEPLER's Law from the observed mean motion  $n$  and adopted mass  $m$ , is 1.0000 0003 (NEWCOMB).

Geocentric coordinates referred to the International Ellipsoid may be calculated from the geographic coordinates by means of Table VII and the formulae

$$\begin{aligned}\rho \sin \phi' &= (S+H) \sin \phi, \\ \rho \cos \phi' &= (C+H) \cos \phi,\end{aligned}$$

where  $S$  and  $C$  are taken from the table, and  $H$  is the altitude above sea-level in units of the equatorial radius of the Earth; the value of  $H$  is obtained by multiplying the altitude (in m) by  $0.1567\ 794 \times 10^{-6}$  (or the altitude in feet by  $0.0477\ 865 \times 10^{-6}$ ).

*Annual rates of precession* (NEWCOMB, *Astr. Pap. Amer. Eph.*, VIII, 73, 1897)

General precession . . . . .	$p = 50''.2564 + 0''.0222\ T$
Planetary precession . . . . .	$\lambda' = 0''.1247 - 0''.0188\ T$
Lunisolar precession . . . . .	$\psi = 50''.3708 + 0''.0050\ T$
Precession in right ascension . . . . .	$m = 3''.07234 + 0''.00186\ T$
Precession in declination . . . . .	$n = 20''.0468 - 0''.0085\ T$

The time  $T$  is measured in tropical centuries from 1900.0. The values of  $p$ ,  $m$ , and  $n$  at the beginning of the Besselian solar year are given on page 50.

These *rates* of the precessional motions at a particular epoch must be carefully distinguished from the accumulated *amounts* of the motions over an extended interval of time, and the consequent displacements of the coordinate systems which the precessional motions produce. The amount of the precession in right ascension during the interval of time from  $t_0$  to  $t$  is  $\zeta_0 + z$ , where  $90^\circ - \zeta_0$  is the right ascension of the ascending node of the mean equator at time  $t$  on the mean equator of  $t_0$  reckoned from the mean equinox of  $t_0$ , and  $90^\circ + z$  is the right ascension of the node reckoned from the mean equinox of  $t$ ; the amount of the precession in declination is the inclination  $\theta$  of the mean equator at time  $t$  to the mean equator of  $t_0$ . For  $t_0 = 1950.0$ , with the interval of time  $T$  from this epoch measured in tropical centuries,

$$\begin{aligned}\zeta_0 &= +2304''.948\ T + 0''.302\ T^2 + 0''.0179\ T^3, \\ z &= +2304''.948\ T + 1''.093\ T^2 + 0''.0192\ T^3, \\ \theta &= +2004''.255\ T - 0''.426\ T^2 - 0''.0416\ T^3.\end{aligned}$$

Interchanging  $t_0$  with  $t$  replaces  $\zeta_0$  by  $-z$ , and  $z$  by  $-\zeta_0$ , and changes the sign of  $\theta$ .

On page 50, the numerical values are given for these precessional displacements of the mean equator and mean equinox during the interval between 1950.0 and the beginning of the current year; and Table III contains values for other intervals. Over a short interval, the values of  $\zeta_0 + z$  and  $\theta$  may be obtained from the rates  $m$  and  $n$  of the precessions at the *midpoint of the interval*, by the formulae

$$M = m(t_0 - t), \quad N = n(t_0 - t).$$

Similarly, the amounts of the general precession in longitude  $a$ , and rotation of the ecliptic  $b$ , may be calculated from the rate of precession  $p$ , and speed of rotation of the ecliptic  $\pi$ , at the midpoint of the interval, by

$$a = p(t_0 - t), \quad b = \pi(t_0 - t).$$

The numerical values of these quantities for the interval between 1950.0 and the current year, and of

$$c = 180^\circ - \Pi + \frac{1}{2}a$$

where  $\Pi$  is the longitude of the axis of rotation of the ecliptic at the midpoint of the interval, are also given on page 50, with formulae for calculating the corresponding precessional variations of equatorial and ecliptic coordinates, and of the ecliptic elements  $\Omega$ ,  $i$ ,  $\omega$ , of an orbit. Expressions for calculating  $\pi$  and  $\Pi$  at any date are given among the elements of the Sun.

### Nutation

The formulae adopted for computing the nutation in longitude and obliquity are given in the joint supplement to the *American Ephemeris* and the *British Nautical Almanac* entitled *Improved Lunar Ephemeris 1952-1959*, pages ix-x (1954). They are obtained by retaining all terms with coefficients as great as 0".0002 from the expressions developed in *Astr. Pap. Amer. Eph.*, vol. XV, Part I, page 153, 1953, and reproduced in *Astr. Jour.*, 58, 2, 1953.

Beginning with 1960, the effects of short-period terms, defined as terms with periods of less than 100 days, are fully included in the ephemerides of the Sun, Moon, and planets.

### Sun (pages 18-50)

The ephemerides of the Sun are derived from the geometric longitude referred to the mean equinox of date, the latitude referred to the ecliptic of date, the radius vector, and the mean obliquity of date, that are taken from NEWCOMB'S *Tables of the Sun*, *Astr. Pap. Amer. Eph.*, vol. VI, Part I, 1895. The mean orbital elements on which these tables are based, with  $T$  denoting the time measured in Julian centuries of 36525 ephemeris days from the epoch, and  $d$  the time in ephemeris days, are:

$$\text{Epoch 1900 January 0.5 E.T.} = \text{J.D. 241 5020.0}$$

Geometric mean longitude, mean equinox of date

$$\begin{aligned} L &= 279^\circ 41' 48".04 + 1296 \ 02768".13 T + 1".089 T^2 \\ &= 279.69668 + 0.98564 \ 73354 d + 0.000303 T^2 \end{aligned}$$

Mean longitude of perigee, mean equinox of date

$$\begin{aligned} \Gamma &= 281^\circ 13' 15".0 + 6189".03 T + 1".63 T^2 + 0".012 T^3 \\ &= 281.22083 + 0.00004 \ 70684 d + 0.000453 T^2 + 0.000003 T^3 \end{aligned}$$

Mean anomaly,  $L - \Gamma$

$$\begin{aligned} g &= 358^\circ 28' 33".0 + 1295 \ 96579".10 T - 0".54 T^2 - 0".012 T^3 \\ &= 358.47583 + 0.98560 \ 02670 d - 0.000150 T^2 - 0.000003 T^3 \end{aligned}$$

Eccentricity

$$e = 0.01675 \ 104 - 0.00004 \ 180 T - 0.00000 \ 0126 T^2$$

The principal related auxiliary constants are:

Mean obliquity of the ecliptic

$$\begin{aligned} \epsilon &= 23^\circ 27' 08".26 - 46".845 T - 0".0059 T^2 + 0".00181 T^3 \\ &= 23.452294 - 0.01301 \ 25 T - 0.00000 \ 164 T^2 + 0.000000 \ 0503 T^3 \end{aligned}$$

Annual rate of rotation of ecliptic	$\pi = 0''.4711 - 0''.0007 T$
Longitude of axis of rotation	$\Pi = 173^\circ 57'.06 + 54'.77 T$
Length of the year	
Tropical	$365^d 2421 9879 - 0^s 0000 0614 T$ $365^d 05^h 48^m 46^s 0 - 0^s 530 T$
Sidereal	$365^d 2563 6042 + 0^s 0000 0011 T$ $365^d 06^h 09^m 09^s 5 + 0^s 01 T$
Anomalistic	$365^d 2596 4134 + 0^s 0000 0304 T$ $365^d 06^h 13^m 53^s 0 + 0^s 26 T$
Eclipse	$346^d 6200 31 + 0^s 0000 32 T$ $346^d 14^h 52^m 50^s 7 + 2^s 8 T$

The longitude of the axis of rotation of the ecliptic is for the extremity that is at the ascending node of the instantaneous position of the ecliptic on the immediately preceding position; and it is referred to the mean equinox of date. The position of the ecliptic in terms of its inclination  $\pi_1$  and node  $\Pi_1$  on the fixed ecliptic of the epoch is represented by

$$\begin{aligned}\pi_1 \sin \Pi_1 &= +4''.964 T + 0''.1939 T^2 - 0''.00019 T^3, \\ \pi_1 \cos \Pi_1 &= -46''.845 T + 0''.0545 T^2 + 0''.00035 T^3.\end{aligned}$$

The values of  $L$  and  $g$  for every tenth day, the values of  $\Gamma$  and  $e$  at the beginning of the calendar year, and of  $\pi$ ,  $\Pi$ , and  $\epsilon$  and the trigonometric functions of  $\epsilon$  for the beginning of the Besselian year, are given on page 50.

The geocentric spherical coordinates of the Sun are tabulated in the ephemeris on pages 18–33; and the geocentric equatorial rectangular coordinates on pages 34–49.

The tabular longitude is the geometric longitude referred to the mean equinox of the beginning of the Besselian year; it may be reduced to the fixed mean equinox of 1950.0 by applying the correction given in the footnote. The values of the latitude referred both to the ecliptic of the beginning of the year and to the fixed ecliptic of 1950.0 are tabulated, in addition to the latitude referred to the ecliptic of date.

The precession in longitude is the amount of the precessional displacement of the equinox along the ecliptic since the beginning of the Besselian year. Adding it to the tabular longitude gives the geometric longitude referred to the mean equinox of date, which may be further reduced to the true equinox of date by adding the nutation in longitude. The precession and nutation in longitude are tabulated to one more decimal than in volumes before 1960; and the nutation includes short-period terms.

The reduction to apparent longitude is the sum of the nutation in longitude at date and the precession from the beginning of the year to date, diminished by aberration which is calculated by dividing  $20''.47$  by the radius vector.

The horizontal parallax is the angle subtended at the Sun by the equatorial radius of the Earth; the tabular values are calculated by dividing  $8''.80$  by the radius vector.

The apparent right ascension and declination are referred to the true equinox and equator of date, and are affected by aberration. They are calculated from the geometric longitude, the latitude referred to the ecliptic of date, and the tabular obliquity of date, which is the sum of the mean obliquity and the nutation in obliquity inclusive of short-period terms; they are corrected for aberration by antedating for the light-time. The value of the radius vector is geometric, not affected by aberration.

The tabular semidiameter includes an allowance for irradiation, and is obtained by dividing an enhanced value of the semidiameter at unit distance by the radius vector, although actually the irradiation does not depend upon the distance; the value adopted for the enhanced semidiameter at unit distance is  $16' 01''.18$ , the same as in the *Nautical Almanac* for years immediately preceding 1960, but different from the value used before 1960 in the *American Ephemeris* because of a different allowance for irradiation. In the calculation of eclipses, the adopted semidiameter at unit distance is  $15' 59''.63$  (AUWERS, *Astronomische Nachrichten*, 3068, 367, 1891), the same as in both the *Nautical Almanac* and the *American Ephemeris* before 1960.

The equation of time, apparent minus mean, is the reduction to be applied to mean solar time in order to obtain the measure of apparent solar time. The tabular value at  $0^h$  E.T. is obtained by subtracting the apparent right ascension of the Sun at  $0^h$  E.T. from the apparent sidereal time of  $0^h$  U.T. increased by  $12^h$ ; the values for 1960 January 0 and January 1 are therefore numerically the same as the tabular values for December 31 and December 32 in the volume for 1959. Since the sidereal time at  $0^h$  U.T. is equal numerically to the right ascension of the fictitious mean sun at  $0^h$  E.T. increased by  $12^h$ , the equation of time determined by this method of calculation is the difference between the right ascensions of the mean sun and the actual Sun, the same as in the volumes before 1960; but the tabular values are for  $0^h$  E.T., not  $0^h$  U.T. as formerly but inexactly designated.

At every instant, the equation of time is rigorously the value of the hour angle of the Sun minus the hour angle of the fictitious mean sun. However, it does not conform exactly to the traditional interpretation as the hour angle of the Sun at local mean noon, because at the instant when the hour angle of the Sun is equal to the equation of time and the mean sun is consequently on the meridian, the local mean time is not precisely  $12^h$ , but  $12^h + 0.002738 \Delta T$ . Likewise, the measure of apparent solar time formally defined by the tabulated equation of time is not precisely the hour angle of the Sun increased by  $12^h$ ; and the Sun does not transit the meridian exactly at local apparent noon.

In terms of the Greenwich hour angle of the Sun  $H$ , the Greenwich apparent solar time at any instant is

$$12^h + H + 0.002738 \Delta T;$$

this measure has no discontinuity from 1959 to 1960.

At Greenwich mean noon,  $12^h$  U.T., the hour angle of the Sun is

$$H = E - 0.002738 \Delta T,$$

where  $E$  denotes the equation of time; and at Greenwich apparent noon,  $12^{\text{h}}$  apparent solar time, the hour angle of the Sun is

$$H = -0.002738 \Delta T.$$

At Greenwich transit of the Sun, when the hour angle of the Sun is zero,

$$\text{U.T.} = 12^{\text{h}} - E + 0.002738 \Delta T;$$

and the apparent solar time is  $12^{\text{h}} + 0.002738 \Delta T$ .

The geocentric rectangular coordinates of the Sun, referred to the mean equator and equinox of the beginning of the year as the fundamental plane and point of reference, are tabulated on pages 34–41, with first and second differences for interpolation; and the rectangular coordinates referred to the mean equator and equinox of 1950.0 are given on pages 42–49. The positive  $X$ -axis is directed toward the equinox, the  $Y$ -axis toward the point on the equator at right ascension  $6^{\text{h}}$ , and the  $Z$ -axis toward the north pole of the equator.

The dates for which the integral part of the Julian Day Number is divisible by 10 are indicated by bold-face type. These are the standard 10-day ephemeris dates recommended by the International Astronomical Union.

#### *Moon (pages 51–159)*

Beginning with the volume for 1960, the lunar ephemeris is calculated directly from BROWN's theory instead of from his *Tables of the Motion of the Moon*; but in order to obtain a strictly gravitational ephemeris expressed in the same measure of time as defined by NEWCOMB's *Tables of the Sun*, the orbital elements upon which BROWN's tables are based were amended by removing the empirical term and by applying to the mean longitude the correction

$$-8''.72 - 26''.74 T - 11''.22 T^2,$$

where  $T$  is measured in Julian centuries from 1900 January 0.5 E.T. = J.D. 2415020.0. A description of the method of calculating the ephemeris, and a comparison of the positions with tabular positions from BROWN's tables, are included in the *Improved Lunar Ephemeris 1952–1959*, which was issued in 1954 to make the amended ephemeris available before 1960.

Denoting by  $d$  the number of ephemeris days from the epoch, the fundamental orbital constants are

$$\begin{aligned} \zeta &= 270^\circ 26' 02''.99 + 1336' 307^\circ 52' 59''.31 T - 4''.08 T^2 + 0''.0068 T^3 \\ &= 270^\circ 434164 + 13^\circ 17639 65268 d - 0^\circ 001133 T^2 + 0^\circ 0000019 T^3, \end{aligned}$$

$$\begin{aligned} \Gamma' &= 334^\circ 19' 46''.40 + 11' 109^\circ 02' 02''.52 T - 37''.17 T^2 - 0''.045 T^3 \\ &= 334^\circ 329556 + 0^\circ 11140 40803 d - 0^\circ 010325 T^2 - 0^\circ 000012 T^3, \end{aligned}$$

$$\begin{aligned} \Omega &= 259^\circ 10' 59''.79 - 5' 134^\circ 08' 31''.23 T + 7''.48 T^2 + 0''.008 T^3 \\ &= 259^\circ 183275 - 0^\circ 05295 39222 d + 0^\circ 002078 T^2 + 0^\circ 000002 T^3, \end{aligned}$$

$$e = 0.05490 0489,$$

$$\gamma = 0.04488 6967,$$

$$\text{constant of sine parallax, } 3422''.5400,$$

where  $\gamma$  is the sine of half the inclination to the ecliptic,  $e$  denotes the eccentricity, and

$\mathcal{C}$ , the mean longitude of the Moon, measured in the ecliptic from the mean equinox of date to the mean ascending node of the lunar orbit, and then along the orbit;

$\Gamma'$ , the mean longitude of the lunar perigee, measured in the ecliptic from the mean equinox of date to the mean ascending node of the lunar orbit, and then along the orbit;

$\Omega$ , the longitude of the mean ascending node of the lunar orbit on the ecliptic, measured from the mean equinox of date.

The equatorial horizontal parallax at distance 60.2665 equatorial radii of the Earth is  $57' 02''.70$ .

In the lunar theory, the adopted ratio of the mass of the Earth to the mass of the Moon is 81.53.

The mean elongation of the Moon from the Sun is

$$D = 350^\circ 44' 14''.95 + 1236' 307^\circ 06' 51''.18 T - 5''.17 T^2 + 0''.0068 T^3 \\ = 350^\circ 737486 + 12^\circ 19074 \ 91914 \ d - 0^\circ 001436 T^2 + 0^\circ 0000019 T^3.$$

The lengths of the months for the epoch 1900 are

	d		d	h	m	s
Synodic . . . . .	29.530	589	29	12	44	02.9
Tropical . . . . .	27.321	582	27	07	43	04.7
Sidereal . . . . .	27.321	661	27	07	43	11.5
Anomalistic . . . . .	27.554	551	27	13	18	33.2
Draconitic . . . . .	27.212	220	27	05	05	35.8

The secular variations do not exceed a few hundredths of a second per century, and depend partly upon the variations in the rate of rotation of the Earth.

The values of  $\Gamma'$ ,  $\Omega$ ,  $\mathcal{C}$ , and  $D$  for every tenth day are tabulated on page

51. This page also contains, for every tenth day, the values of

$i$ , the inclination of the mean equator of the Moon to the true equator of the Earth,

$\Delta$ , the arc of the mean equator of the Moon from its ascending node on the true equator of the Earth to its ascending node on the ecliptic of date,

$\Omega'$ , the arc of the true equator of the Earth from the true equinox of date to the ascending node of the mean equator of the Moon,

calculated with HAYN's value of  $1^\circ 32'.1$  for the inclination of the mean lunar equator to the ecliptic; the ascending node of the mean lunar equator on the ecliptic is at the descending node of the mean lunar orbit,  $\Omega \pm 180^\circ$ .

The coordinates of the Moon are tabulated to one more decimal than in volumes preceding 1960.

The longitude referred to the mean equinox of date, the latitude referred to the ecliptic of date, and the horizontal parallax are computed for every half-day from BROWN's theoretical expressions, with the corrections required for the amendment to the mean longitude. The apparent longitude and lati-

tude are obtained by adding the nutation in longitude and some residual effects of aberration not included in BROWN's expressions.

The semidiameter,  $s$ , is derived from the horizontal parallax,  $\pi$ , by the formula

$$s = 0''.079 + 0.272446 \pi,$$

the constants in which are based on NEWCOMB's value of  $15' 32''.58$  for the semidiameter at mean distance (Researches on the Motion of the Moon, Part II, *Astr. Pap. Amer. Eph.*, Vol. IX, 39, 1912). No correction is made for irradiation.

The apparent right ascension and declination for each hour of Ephemeris Time (pages 68–159) are calculated for  $0^h$  and  $12^h$  from the apparent longitude, the apparent latitude, and the true obliquity of date; and for the other hours by interpolation.

Page 159 contains the phases of the Moon, and the times of apogee and perigee or greatest and least distances from the Earth. The times of New Moon, First Quarter, Full Moon and Last Quarter are the times at which the excess of the apparent longitude of the Moon over the apparent longitude of the Sun is  $0^\circ$ ,  $90^\circ$ ,  $180^\circ$ , and  $270^\circ$ , respectively.

#### *The Principal Planets (pages 160–235)*

Heliocentric ephemerides of the principal planets are given on pages 160–176, followed on pages 176–177 by the values of the orbital elements during the year. Geocentric ephemerides, calculated from the heliocentric coordinates of the planets and the geocentric coordinates of the Sun, are given on pages 178–235.

The ephemerides of the *inner planets* Mercury, Venus, and Mars are obtained from the same tables as for years immediately preceding 1960. The orbital longitudes and the heliocentric ecliptic longitudes referred to the mean equinox of date, the heliocentric latitudes referred to the ecliptic of date, and the radius vectors are taken from NEWCOMB's tables of these planets in *Astr. Pap. Amer. Eph.*, Vol. VI, Parts II, III, IV, 1895–1898; for Mars, the corrections derived by Ross, *Astr. Pap. Amer. Eph.*, Vol. IX, Part II, 1917, are applied. The elements of the mean orbits are tabulated on page 176. For Venus and Mars, the latitude referred to the mean orbit, due to periodic perturbations in latitude, is included in the heliocentric ephemerides.

The ephemerides of the *outer planets* Jupiter, Saturn, Uranus, Neptune, and Pluto, beginning with 1960, are computed from the heliocentric rectangular coordinates obtained by numerical integration in *Astr. Pap. Amer. Eph.*, Vol. XII, 1951. Perturbations by the inner planets, taken from *Astr. Pap. Amer. Eph.*, Vol. XIII, Part V, 1954, are included in the geocentric ephemerides, but are omitted from the heliocentric ephemerides, and from the heliocentric orbital elements tabulated on page 177; these elements are for the osculating orbits. The geocentric right ascensions and declinations of the outer planets are tabulated to one more decimal than for years preceding 1960.

In these tables and ephemerides, the values adopted for the masses of the planets, including atmospheres and satellites, are:

	Reciprocal Mass		Reciprocal Mass
Mercury . . .	6 000 000	Uranus . . . . .	22 869
Venus . . . .	408 000	Neptune	
Earth . . . .	329 390	In tables of five outer planets . .	19 314
Mars . . . .	3 093 500	In tables of four inner planets . .	19 700
Jupiter . . .	1 047.355	Pluto . . . . .	360 000
Saturn . . . .	3 501.6		

In the planetary theory, the adopted ratio of the mass of the Earth to the mass of the Moon is 81.45; and the ratio of the mass of the Sun to the mass of the Earth alone, 333 432.

In the geocentric ephemerides, the *apparent* right ascension and declination are referred to the true equator and equinox of date, inclusive of the short-period terms of nutation; and they have been corrected for planetary aberration by antedating for the light-time.

The *astrometric* positions of Pluto and the minor planets are obtained by adding the planetary aberration to the geometric ephemeris and then subtracting stellar aberration, calculated by the conventional formula which neglects the part depending on the longitude of the perihelion of the Earth. The astrometric ephemeris is therefore rigorously comparable with observations that are referred to catalogue mean places of comparison stars, it being only necessary to correct the observations for geocentric parallax.

The tabular true distance from the Earth is the actual geocentric distance at the tabular time, *not* at the instant when the light that reaches the observer at the tabular time left the planet.

The horizontal parallax is  $8''.80$  divided by the geocentric distance. The tabular semidiameter is the value at unit distance divided by the geocentric distance; the adopted semidiameters at unit distance are:

Mercury . . . . .	3''.34	LE VERRIER, <i>Liouville's Journal</i> , Tome VIII, 279, 1843.
Venus . . . . .	8''.41	AUWERS, <i>Astronomische Nachrichten</i> 3214, page 361, 1894.
Mars. . . . .	4''.68	HARTWIG, <i>Publikation der Astronomischen Gesellschaft</i> , vol. XV, 77, 1879.
Jupiter:		
Equatorial . . . . .	98''.47	SAMPSON, <i>Tables of the Four Great Satellites of Jupiter</i> , pages xvi, xxi, 1910.
Polar. . . . .	91''.91	
Saturn:		
Equatorial . . . . .	83''.33	H. STRUVE, <i>Pub. de l'Obs. Central Nicolas</i> , Série II, vol. XI, 207, 1898.

Uranus . . . . .	34''.28	Weighted mean of: BARNARD, <i>Astr. Jour.</i> , vol. XVI, 75, 1896; T. J. J. See, <i>Astronomische Nachrichten</i> 3768, page 399, 1902; WIRTZ, <i>Annalen der Kaiserlichen Universitäts-Sternwarte in Strassburg</i> , Band 4, Teil II, 285, 1912.
Neptune . . . . .	36''.56	BARNARD, <i>Astr. Nachr.</i> 3760, 266, 1902.

*Minor Planets (pages 236-265)*

The ephemerides of Ceres, Pallas, Juno, and Vesta are computed from unpublished heliocentric rectangular coordinates calculated by PAUL HERGET by means of numerical integration with the Naval Ordnance Research Calculator (NORC). An adaptation of HANSEN's method was used, with a 10-day interval. The integrations were adjusted along the entire orbits to the previous integrations that were used for the ephemerides before 1960; a smooth join-on at 1960 was obtained by taking most of the equations of condition near this epoch. Differences from the previous orbits are attributable to accumulation of rounding errors in the former integrations. The largest discontinuity at 1960 is 0".07 for Vesta, which is smaller than the amounts that may be reached by the non-gravitational parts of the previous coordinates.

The ephemerides are in the same form as for Pluto, with the addition of the reductions from astrometric to apparent right ascension and declination. Daily positions are given for the periods during which the planet is more than about 40° from the Sun. Since accurate observations of the minor planets may lead to an improved value for the mass of the Moon, the dates on which the lunar inequality is a maximum in right ascension are indicated by an asterisk.

**Stars**

The star places that are given in this volume are limited to the mean places of the brighter stars at the beginning of the Besselian year, to an accuracy of 0".1 in right ascension and 1" in declination. However, the volume contains all the data necessary for the accurate reduction of precise star places from one epoch to another, or from mean place to apparent place.

*Day Numbers (pages 266-287)*

The Besselian Day Numbers and the Independent Day Numbers for calculating reductions from the mean place to the apparent place are given for 0<sup>h</sup> Ephemeris Time on pages 266-281, to one more decimal than in volumes immediately preceding 1960; the sidereal time at 0<sup>h</sup> Ephemeris Time, to the nearest tenth of an hour, is tabulated with these Day Numbers to assist in determining the interpolating factor for the time of meridian transit of a star. The Besselian Day Numbers at 0<sup>h</sup> Greenwich sidereal time are tabulated on pages 282-285.

From these Day Numbers, the reduction for precession, nutation, and aberration is obtained to the first order. The additional Day Numbers necessary to determine the reduction to the second order are given on pages 286-287.

To avoid a second-order reduction as far as possible, the Day Numbers, beginning with 1960, are referred to the *nearest* beginning of a year, instead of always to the beginning of the current year. For any tabular date,  $\tau$  denotes the fraction of a tropical year that has elapsed since the date to which the tabular values of the Day Numbers are referred; and the apparent place is obtained with these Day Numbers from the mean place at the beginning of either the *current* Besselian year or the *next following* year, according to the

tabular value of  $\tau$ . By not extending the reduction over more than half a year, the second-order reduction and the error from neglecting it are kept as small as practicable.

The reductions to the second order are

$$\begin{aligned}\alpha &= \alpha_0 + Aa + Bb + Cc + Dd + E + J \tan^2 \delta \\ &= \alpha_0 + f + g \sin (G + \alpha_0) \tan \delta_0 + h \sin (H + \alpha_0) \sec \delta_0 + J \tan^2 \delta, \\ \delta &= \delta_0 + Aa' + Bb' + Cc' + Dd' + J' \tan \delta \\ &= \delta_0 + g \cos (G + \alpha_0) + h \cos (H + \alpha_0) \sin \delta_0 + i \cos \delta_0 + J' \tan \delta,\end{aligned}$$

where zero subscripts denote the mean place, and

$$\begin{aligned}a &= \frac{m}{n} + \sin \alpha_0 \tan \delta_0, & a' &= \cos \alpha_0, \\ b &= \cos \alpha_0 \tan \delta_0, & b' &= -\sin \alpha_0, \\ c &= \cos \alpha_0 \sec \delta_0, & c' &= \tan \epsilon \cos \delta_0 - \sin \alpha_0 \sin \delta_0, \\ d &= \sin \alpha_0 \sec \delta_0, & d' &= \cos \alpha_0 \sin \delta_0,\end{aligned}$$

which are known as the Besselian Star Constants; in the second-order terms, or in a reduction to only the first order, it is immaterial whether the mean or the apparent values of the coordinates are used in the right-hand members. Further reductions are also required for proper motion and for parallax, as far as they are known and of appreciable magnitude; and in the case of binary stars, a correction for orbital motion may be necessary. The tabular values of the Day Numbers  $A, B, C, D, g, h, i$ , are in seconds of arc; when used for reducing right ascension, either they or the star constants by which they are multiplied must be divided by 15 to express the reduction in seconds of time.

The Besselian Day Numbers  $A, B$ , and  $E$ , or the Independent Day Numbers  $f, g$ , and  $G$ , give the reduction for precession and nutation. Beginning with 1960, they are derived from the improved values of the nutation, including short-period terms; and  $A$  is redefined as the product of the former value by the precession in declination,  $n$ , in order to express it in seconds of arc. Before 1960, the star constants  $a$  and  $a'$  were defined as  $a = m + n \sin \alpha_0 \tan \delta_0$ ,  $a' = n \cos \alpha_0$ . The short-period terms of nutation in longitude and obliquity,  $d\psi$  and  $d\epsilon$ , respectively, and the Day Numbers  $f', g', G'$ , for obtaining the effects of these terms alone, are also tabulated on pages 266–281.

The Day Numbers  $C$  and  $D$ , or  $H, h$ , and  $i$ , give the reduction for aberration; beginning with 1960, they are derived from the actual disturbed velocity of the Earth referred to the center of mass of the solar system.

The Besselian Day Numbers are the most expeditious means of reduction when several apparent positions of the same star are required, or when the values of the Besselian star constants are already available; otherwise, the Independent Day Numbers are the more convenient.

## Example

To illustrate the calculation of an apparent place for a date in any part of the year, by means of either the Besselian or the Independent Day Numbers, the apparent place of  $\alpha$  Coronae Borealis for the upper transit at Greenwich on July 1 is obtained in the following example both by a reduction from the mean place at the beginning of the year, using the Besselian Day Numbers, and by a reduction from the mean place at the beginning of the next following year, using the Independent Day Numbers; for this date, the Day Numbers are given for both epochs in the ephemeris.

From Kopff's *Dritter Fundamentalkatalog des Berliner Astronomischen Jahrbuchs* (FK3), the mean place is:

	1960.0	1961.0
$\alpha_0$	15 <sup>h</sup> 32 <sup>m</sup> 59 <sup>s</sup> .556	15 <sup>h</sup> 33 <sup>m</sup> 02 <sup>s</sup> .097
$\delta_0$	+ 26° 50' 53".77	+ 26° 50' 41".69

The time of upper transit, to an accuracy sufficient for interpolating the Day Numbers, is  $\alpha_0 - \text{S.T. } 0^{\text{h}} = \text{July } 1^{\text{d}}871$ .

The Day Numbers including short-period terms, interpolated with second differences, and the star constants, are:

1960 July 1<sup>d</sup>871

$\tau$	+ 0.4998	$\tau$	- 0.5002
$A$	+ 8".814	$f$	- 1 <sup>s</sup> .7223
$B$	+ 9".572	$g$	14".754
$C$	+ 3".262	$G$	9 <sup>h</sup> 18 <sup>m</sup> 12 <sup>s</sup>
$D$	- 20".148	$h$	20".411
$E$	- 0 <sup>s</sup> .0005	$H$	11 <sup>h</sup> 23 <sup>m</sup> 10 <sup>s</sup>
		$i$	+ 1".417
$a$	+ 1.8947	$G + \alpha_0$	0 <sup>h</sup> 51 <sup>m</sup> 14 <sup>s</sup>
$b$	- 0.3029	$H + \alpha_0$	2 56 12
$c$	- 0.6707		
$d$	- 0.8980		
$a'$	- 0.5984		
$b'$	+ 0.8012		
$c'$	+ 0.7488		
$d'$	- 0.2702		

The second-order Day Numbers are not required as their contribution is inappreciable. The annual proper motions are  $\mu = + 0^{\text{s}}009$ ,  $\mu' = - 0^{\text{s}}09$ .

*Besselian reduction from 1960.0*

$\alpha_0$	15 <sup>h</sup> 32 <sup>m</sup> 59 <sup>s</sup> .556	$\delta_0$	+26° 50' 53".77
<i>Aa</i>	+ 1.1133	<i>Aa'</i>	— 5.274
<i>Bb</i>	— 0.1933	<i>Bb'</i>	+ 7.669
<i>Cc</i>	— 0.1459	<i>Cc'</i>	+ 2.443
<i>Dd</i>	+ 1.2062	<i>Dd'</i>	+ 5.444
<i>E</i>	— 0.0005		
$\tau\mu$	+ 0.0045	$\tau\mu'$	— 0.045
$\alpha$	15 <sup>h</sup> 33 <sup>m</sup> 01 <sup>s</sup> .540	$\delta$	+26° 51' 04".01

*Reduction from 1961.0, with Independent Day Numbers*

$\alpha_0$	15 <sup>h</sup> 33 <sup>m</sup> 02 <sup>s</sup> .097	$\delta_0$	+26° 50' 41".69
<i>f</i>	— 1.7223	$g \cos (G + \alpha_0)$	+14.387
$g \sin (G + \alpha_0) \tan \delta_0$	+ 0.1104	$h \cos (H + \alpha_0) \sin \delta_0$	+ 6.625
$h \sin (H + \alpha_0) \sec \delta_0$	+ 1.0604	$i \cos \delta_0$	+ 1.264
$\tau\mu$	— 0.0045	$\tau\mu'$	+ 0.045
$\alpha$	15 <sup>h</sup> 33 <sup>m</sup> 01 <sup>s</sup> .541	$\delta$	+26° 51' 04".01

Positions calculated by different methods may sometimes differ by a unit in the end figure.

Reductions for precession and nutation directly from the standard equinox of 1950.0 to the true equinox of date may be obtained with sufficient accuracy for a finding ephemeris of a comet or a minor planet by means of Table IV, in accordance with the formulae at the foot of the table. The tabular dates are the midnights following an integral Julian Date that is exactly divisible by 10, in accordance with the resolutions of the International Astronomical Union that the osculation epochs of elements of comets and minor planets should be Julian Dates with the integral part divisible by 400, and that ephemerides should be for 10-day intervals. Dates followed by an asterisk are the Julian Dates with integral part divisible by 40.

To facilitate the reduction of observations in which the differences of right ascension and declination between two celestial objects are measured, the differential aberration and the differential precession and nutation may be determined from Tables V and VI in accordance with the precepts given with the tables. With the position of a star reduced to the equinox of 1950.0, or to the equinox of the nearest beginning of a year, the coordinates of an object referred to the same equinox are obtained by adding to the coordinates of the star the observed differences in the sense "object minus star", and the differential aberration, precession, and nutation taken from these tables.

*Mean Places of Stars (pages 288–298)*

Mean places at the beginning of the Besselian year are tabulated for 1078 stars, including stars to a limiting magnitude 4.75 excepting 8 stars each within 30" of an included star; variable stars are in general included if the maximum is brighter than 4.7. The positions are taken from the Albany *General Cata-*

*logue of 33342 Stars for the Epoch 1950, 1937.* The stars are tabulated in the order of their mean right ascensions at the epoch 1950.0. In the name of the star, the three-letter abbreviations for constellation names recommended by the International Astronomical Union are used.

Disregarding proper motion, which is generally much less than a second of arc per year, the mean places at other epochs may be obtained by a reduction for precession alone. In particular, to obtain the mean place at the beginning of the next following year, which is required for calculating reductions from mean to apparent places with the tabular Day Numbers during the latter half of the current year, add to the tabular coordinates the reductions

$$\begin{aligned}\Delta\alpha &= m + n \sin \alpha \tan \delta, \\ \Delta\delta &= n \cos \alpha,\end{aligned}$$

where the values of  $m$  and  $n$  are taken from page 50. Formulae and constants for the reduction of right ascension and declination, and of longitude and latitude, for precession from the beginning of the current year to 1950.0 and in the reverse direction, are also given on page 50; and an extended tabulation of the equatorial precessional constants for other intervals is given in Table III.

Table III contains the reduction constants  $\zeta_0$ ,  $z$ , and  $\theta$  for rigorous trigonometric reductions of mean places to the beginning of the current year from the beginning of each fifth previous year back to 1825 and other selected years back to 1755; and also the coefficients  $M$  and  $N$  for approximate reductions with the formulae on page 50. The table is calculated from formulae derived from NEWCOMB'S numerical expressions for the precessional displacements of the mean equator, *Astr. Pap. Amer. Eph.*, Vol. VIII, page 75, 1897;  $M$  and  $N$  are obtained from the rates of change of  $z + \zeta_0$  and  $\theta$  at the time midway from  $t_0$  to  $t$ . With the tabular constants, rigorous reductions of the coordinates  $\alpha_0$ ,  $\delta_0$ , referred to the mean equinox of  $t_0$ , to the coordinates  $\alpha$ ,  $\delta$ , referred to the mean equinox of the beginning of the current year, may be calculated from the formulae

$$\begin{aligned}q &= \sin \theta [\tan \delta_0 + \cos (\alpha_0 + \zeta_0) \tan \tfrac{1}{2} \theta], \\ \tan (\Delta\alpha - \mu) &= \frac{q \sin (\alpha_0 + \zeta_0)}{1 - q \cos (\alpha_0 + \zeta_0)}, \\ \mu &= \zeta_0 + z, \\ \alpha &= \alpha_0 + \Delta\alpha, \\ \tan \tfrac{1}{2} (\delta - \delta_0) &= \tan \tfrac{1}{2} \theta \sec \tfrac{1}{2} (\Delta\alpha - \mu) \cos [(\alpha_0 + \zeta_0) + \tfrac{1}{2} (\Delta\alpha - \mu)].\end{aligned}$$

### Eclipses (pages 299–305)

Elements and general circumstances are given for all solar and lunar eclipses, including penumbral lunar eclipses, which occur during the year. For solar eclipses, maps are given from which approximate local circumstances may be obtained for any particular place; and the Besselian elements are tabulated at 10-minute intervals for the calculation of accurate predictions for any point on or above the surface of the Earth. For total or annular eclipses the latitudes and longitudes of points on the central line and on the northern

and southern limits, together with the duration of the total or annular phase and the altitude of the Sun on the central line, are tabulated at intervals of five minutes or less throughout the eclipse. For lunar eclipses, the circumstances and their Ephemeris Times or Universal Times are the same for all parts of the Earth; any particular phase is visible from the hemisphere over which the Moon is then above the horizon.

The elements and circumstances are computed in accordance with BESSEL'S method, for the International Ellipsoid, from apparent right ascensions and declinations of the Sun and Moon which include the short-period terms of nutation; and the coordinates of the Sun for this purpose are calculated to an additional decimal. The semidiameters of the Sun and Moon used in the calculation of eclipses do not include irradiation. The adopted semidiameter of the Sun at unit distance is  $15' 59''.63$  (AUWERS, *Astronomische Nachrichten*, 3068, 367, 1891), the same, except for irradiation, as in the ephemeris of the Sun; but the apparent semidiameter of the Moon is calculated by putting its sine equal to  $0.272274 \sin \pi$ , where  $\pi$  is the horizontal parallax, and differs from the tabular value in the ephemeris of the Moon.

In the calculation of lunar eclipses, the radius of the geometric shadow of the Earth is increased by one-fiftieth part to allow for the effect of the atmosphere. Otherwise, refraction is neglected in computing solar and lunar eclipses. The Besselian elements do not involve refraction. The circumstances of eclipses are calculated for the surface of the ellipsoid, and the inclusion of refraction in them would be inappropriate. For local predictions, corrections for refraction are unnecessary; they are required only in precise comparisons of theory with observation, in which many other refinements are also necessary.

The magnitude of a solar eclipse is the fraction of the solar diameter obscured by the Moon at greatest phase, measured along the common diameter. The magnitude of a lunar eclipse is the fraction of the lunar diameter obscured by the shadow of the Earth at greatest phase, measured along the common diameter.

On the solar eclipse maps, the curves drawn in long dashes indicate the times halfway between first and last contacts of the penumbra. These times of the middle of the eclipse should not be confused with the times of greatest eclipse, from which they may differ by several minutes. The curves drawn in short dashes give the semiduration of the partial phase. The Ephemeris Times of first and last contacts are derived from the time of middle by respectively subtracting and adding the semiduration. The curves are extended across the rising and setting limits of the eclipse, although part of the phenomenon occurs below the horizon for observers in those regions.

The Besselian elements characterize the geometric position of the shadow of the Moon relative to the Earth. The exterior tangents to the surfaces of the Sun and the Moon form the umbral cone, the interior tangents the penumbral cone. The common axis of the two cones is the axis of the shadow. The geocentric plane perpendicular to the axis of the shadow is called the fundamental plane, and is taken as the  $xy$ -plane of a system of geocentric rectangular coordinates. The  $x$ -axis is the intersection of the fundamental plane with the

plane of the equator, and is directed positively toward the east; the  $y$ -axis is directed positively toward the north. The  $z$ -axis is parallel to the axis of the shadow, and is positive toward the Moon. The tabular  $x$  and  $y$  are the coordinates of the intersection of the axis of the shadow with the fundamental plane, in units of the equatorial radius of the Earth. The declination  $d$  and ephemeris hour angle  $\mu$  of the point on the celestial sphere toward which the axis of the shadow is directed represent the direction of the axis.

The radius of the penumbral cone on the fundamental plane is denoted by  $l_1$ ; the radius of the umbral cone is  $l_2$ , and is regarded as positive for an annular eclipse, negative for a total eclipse. The angles  $f_1$  and  $f_2$  are the angles which the elements of the penumbral and the umbral cones, respectively, make with the axis of the shadow.

To predict accurate local circumstances, calculate the geocentric coordinates  $\rho \sin \phi'$  and  $\rho \cos \phi'$  from the geodetic latitude  $\phi$  and longitude  $\lambda$ , with Table VII, page 465, and the formulae on page 497; the inclusion of the elevation above sea level in this calculation is all that is necessary to obtain the local circumstances at high altitudes or in the ionosphere. Obtain approximate times for the beginning, middle, and end of the eclipse from the eclipse map; and for each of these three times, take from the table of Besselian elements the values of  $x$ ,  $y$ ,  $\sin d$ ,  $\cos d$ ,  $\mu$ , and  $l_1$ , except that for the middle  $l_2$  is needed instead of  $l_1$  where the eclipse is total or annular. The hourly variations  $x'$ ,  $y'$ , of  $x$  and  $y$  are needed, and may be obtained with sufficient accuracy by multiplying the first differences of the tabular values by 6.

For each of the three approximate times, calculate the coordinates  $\xi$ ,  $\eta$ ,  $\zeta$  of the observer, and the hourly variations  $\xi'$ ,  $\eta'$ , neglecting the variation of  $d$ , from

$$\begin{aligned}\xi &= \rho \cos \phi' \sin h, \\ \eta &= \rho \sin \phi' \cos d - \rho \cos \phi' \sin d \cos h, \\ \zeta &= \rho \sin \phi' \sin d + \rho \cos \phi' \cos d \cos h, \\ \xi' &= \mu' \rho \cos \phi' \cos h, \\ \eta' &= \mu' \xi \sin d,\end{aligned}$$

where

$$h = \mu - \lambda - 1.0027 \Delta T.$$

Next, calculate

$$\begin{aligned}u &= x - \xi, & u' &= x' - \xi', \\ v &= y - \eta, & v' &= y' - \eta', \\ L &= l - \zeta \tan f, & n^2 &= u'^2 + v'^2, & (n > 0) \\ \Delta &= \frac{1}{n} (uv' - u'v), & D &= uu' + vv',\end{aligned}$$

$$\sin \psi = \frac{\Delta}{L}.$$

Neglecting the variation of  $L$ , the correction  $\tau$  to the assumed time of middle to obtain the *Ephemeris Time of greatest phase* is

$$\tau = -\frac{D}{n^2},$$

which may be expressed in minutes by multiplying by 60.

The correction  $\tau$  to the assumed times of beginning, middle and end to obtain the *Ephemeris Times of contacts* is

$$\tau = \frac{L}{n} \cos \psi - \frac{D}{n^2},$$

which may be expressed in minutes by multiplying by 60.

The ambiguity in the quadrant of  $\psi$  is removed by noting that  $\cos \psi$  must be negative for the beginning of the eclipse, for the beginning of the annular phase, and for the end of the total phase, and that  $\cos \psi$  must be positive for the end of the eclipse, the end of the annular phase and the beginning of the total phase.

If the eclipse is partial at the place the quantities  $l_2$ ,  $L_2$  and  $\sin \psi$  will not be needed for the time of middle.

For greater accuracy, the times resulting from the calculation outlined above should be taken in place of the original approximate times, and a second approximation performed.

The adopted value of  $\Delta T$  must be subtracted from the final times to obtain the Universal Times of contacts and greatest phase.

The *magnitude of greatest partial eclipse*, in units of the solar diameter, is

$$M_1 = \frac{L_1 - \Delta}{2L_1 - 0.5459},$$

where the absolute value of  $\Delta$  is used.

The *magnitude of the central phase*, in the same units, is

$$M_2 = \frac{0.5459}{2L_1 - 0.5459}.$$

In order to obtain the *position angle of a point of contact*, calculate the angle  $N$  defined by

$$\cot N = \frac{v'}{u'},$$

$\sin N$  having the same algebraic sign as  $u'$ . The position angle  $P$  of the point of contact, reckoned from the north point of the solar limb toward the east, is

$$P = N + \psi,$$

where the results of the final approximation are used.

The position angle  $V$  of the point of contact, reckoned from the vertex of the solar limb toward the east is

$$V = P - C,$$

where  $C$ , the parallactic angle, is obtained with sufficient accuracy from

$$\tan C = \frac{\xi}{\eta},$$

$\sin C$  having the same algebraic sign as  $\xi$ , and the results of the final approximation again being used.

At any locality within several miles of a point for which the preceding computation has been made, the Ephemeris Times of the phases may be obtained by computing differential corrections in which most of the necessary numerical quantities are already available from the previous calculations.

Let

$$\begin{aligned} A_1 &= -\rho \cos \phi' \cos h, \\ B_1 &= -\xi \sin d, \\ A_2 &= -(SC^2 + H) \sin \phi \sin h, \\ B_2 &= (SC^2 + H) (\cos \phi \cos d + \sin \phi \sin d \cos h), \\ A_3 &= \cos \phi \sin h, \\ B_3 &= \sin \phi \cos d - \cos \phi \sin d \cos h. \end{aligned}$$

The Ephemeris Times of first and last contacts at longitude  $\lambda + \Delta\lambda$ , latitude  $\phi + \Delta\phi$ , elevation  $H + \Delta H$ , are obtained by adding to the exact times at the position  $\lambda, \phi, H$ , the correction, in seconds,

$$T' = p\Delta\lambda + q\Delta\phi + r\Delta H,$$

where  $\Delta\lambda$  and  $\Delta\phi$  are in minutes of arc,  $\Delta H$  is in units of the equatorial radius of the Earth and  $p, q, r$  are given by

$$\begin{aligned} p &= \frac{\sin 1'}{D} (uA_1 + vB_1), \\ q &= \frac{\sin 1'}{D} (uA_2 + vB_2), \\ r &= \frac{1}{D} (uA_3 + vB_3). \end{aligned}$$

The quantities  $p, q, r$ , are to be expressed in seconds by multiplying by 3600.

The Ephemeris Time of middle of central phase, or time of greatest eclipse if the eclipse is partial only, at  $\lambda + \Delta\lambda, \phi + \Delta\phi, H + \Delta H$ , is obtained by adding to the corresponding time  $T_m$  at  $\lambda, \phi, H$ , the correction, in seconds,

$$T'_m = p_m\Delta\lambda + q_m\Delta\phi + r_m\Delta H,$$

where

$$\begin{aligned} p_m &= \frac{\sin 1'}{n^2} (u'A_1 + v'B_1), \\ q_m &= \frac{\sin 1'}{n^2} (u'A_2 + v'B_2), \\ r_m &= \frac{1}{n^2} (u'A_3 + v'B_3). \end{aligned}$$

These three quantities must be expressed in seconds by multiplying by 3600.

When the eclipse is total or annular at  $\lambda + \Delta\lambda, \phi + \Delta\phi, H + \Delta H$ , the Ephemeris Times of second and third contacts are

$$T_2 = T_m + T'_m - s, \quad T_3 = T_m + T'_m + s,$$

in which  $s$  is the semiduration of central phase. In order to compute  $s$  the value

of  $\Delta$  in the final approximation of the time of middle at  $\lambda, \phi, H$ , must receive the correction

$$\Delta' = p_s \Delta \lambda + q_s \Delta \phi + r_s \Delta H,$$

where

$$p_s = \frac{\sin 1'}{n} (u' B_1 - v' A_1),$$

$$q_s = \frac{\sin 1'}{n} (u' B_2 - v' A_2),$$

$$r_s = \frac{1}{n} (u' B_3 - v' A_3).$$

Then

$$\sin \psi_1 = \frac{1}{L_2} (\Delta + \Delta')$$

and

$$s = \pm \frac{L_2}{n} \cos \psi_1,$$

always taken as positive, and expressed in seconds by multiplying by 3600.

To obtain the angle  $C$  for second and third contacts at  $\lambda + \Delta \lambda, \phi + \Delta \phi, H + \Delta H$ , use the equation

$$\tan C = \frac{\xi \mp \xi' s}{\eta \mp \eta' s},$$

in which upper signs are for second contact, lower signs for third;  $\xi, \eta, \xi', \eta'$  are for the middle of the eclipse at  $\lambda, \phi, H$ . In this equation  $s$  is to be expressed in hours; and  $\sin C$  has the same algebraic sign as  $(\xi \mp \xi' s)$ .

The angles  $P$  and  $V$  are

$$\begin{aligned} P &= N + \psi_1, \\ P - C &= V, \end{aligned}$$

where  $N$  may be assumed constant in this instance;  $\psi_1$  is obtained from the computation of  $s$ . In determining the quadrant of  $\psi_1$  for the two contacts, note that in a total eclipse  $\cos \psi_1$  is positive for second contact, negative for third, the reverse in an annular eclipse.

As before, the value of  $\Delta T$  must be subtracted from the final Ephemeris Times in order to obtain the Universal Times.

In general, the *finally adopted value of  $\Delta T$*  will differ somewhat from the value used in the predictions. It will not be necessary, however, to repeat the whole calculation for  $\phi, \lambda, H$ . If the final value is equal to  $\Delta T + \Delta' T$ , it is sufficient to set

$$\Delta \lambda = 1.0027 \Delta' T, \quad \Delta \phi = 0, \quad \Delta H = 0,$$

and to compute  $T', T'_m$  and  $s$  as outlined above. It may be noted that only the quantities  $A_1, B_1, p, p_m$  and  $p_s$  will be required. The value  $\Delta T + \Delta' T$  must be subtracted from the Ephemeris Times in order to obtain the Universal Times.

### Ephemerides for Physical Observations

The ephemerides for physical observations of the Sun, Moon, and planets are based on the fundamental ephemerides in the preceding part of the volume, and on the additional data to which specific references are made. The tabular values are affected by aberration, and should therefore be interpolated to the actual time of observation; but they are strictly geocentric. They are given to a degree of accuracy sufficient for the reduction of observations, and any significant approximations made in their calculation are stated.

The value of the light-time for unit distance used in calculating the physical ephemerides is 498<sup>s</sup>.58, corresponding to the adopted values of the solar parallax and velocity of light. The stellar magnitudes of the planets are obtained from the formulae of G. MÜLLER, *Publicationen des Astrophysikalischen Observatoriums zu Potsdam*, 8, 366, 1893; the diameters of the planets are calculated from the same semidiameters at unit distance as in the fundamental ephemerides.

#### *Ephemeris for Physical Observations of the Sun (pages 310-315)*

This ephemeris is calculated from the elements determined by CARRINGTON, *Observations of the Spots on the Sun*, pages 221, 244, 1863:

Inclination of the solar equator to the ecliptic,  $7^{\circ} 15'$ ;

Longitude of the ascending node of the solar equator on the ecliptic,  
 $73^{\circ} 40' + 50''25 t$ , where  $t$  is the time in years reckoned from 1850;

Sidereal period of rotation, 25.38 mean solar days.

In the ephemeris,  $P$  denotes the position angle of the northern extremity of the axis of rotation, measured eastward from the north point of the disk;  $B_0$ , the heliographic latitude, and  $L_0$ , the heliographic longitude, of the central point of the disk. Heliographic longitudes on the surface of the Sun are measured from the solar meridian that passed through the ascending node of the solar equator on the ecliptic on 1854 January 1, Greenwich mean noon (J. D. 239 8220.0); they are reckoned from  $0^{\circ}$  to  $360^{\circ}$ , in the direction of rotation, i. e., westward on the apparent disk as viewed on the celestial sphere. CARRINGTON'S zero meridian passed the ascending node twelve hours earlier.

The synodic period of rotation is the interval of time during which  $L_0$  decreases by  $360^{\circ}$ . The mean synodic period is 27<sup>d</sup>2753. The beginning of each synodic rotation is the instant at which  $L_0$  passes through  $0^{\circ}$ ; the rotations are numbered in continuation of CARRINGTON'S Greenwich photo-heliographic series, of which No. 1 commenced on 1853 November 9.

In computing the physical ephemeris of the Sun, no allowance for the secular motion of the ecliptic is made in the values of the elements; and the latitude of the Sun is neglected. No correction is applied to  $L_0$  for rotation during the light-time, since presumably it is already included in CARRINGTON'S meridian; CARRINGTON, in reducing his observations, added  $20''$  for aberration to the tabular longitude of the Sun taken from the *Nautical Almanac*, but he appears to have referred his measurements to the *apparent* central point of the disk. By using the apparent longitude of the Sun in calculating the physical ephem-

eris, the aberration in longitude is included; and no further correction for aberration is required. For convenience of calculation, however, it has been the practice to use formulae which only partially take account of the aberration in longitude, since the error introduced into  $P$  and  $B_0$  is inappreciable, and the error in  $L_0$ , though at maximum it can amount to about  $20''$ , has not been considered important.

*Ephemeris for Physical Observations of the Moon (pages 316-325)*

In the computation of this ephemeris, the formulae and constants for the physical librations, and the value  $1^\circ 32'.1$  for the inclination of the mean lunar equator to the ecliptic, that were determined by HAYN, *Abh. d. Math.-phys. Kl. d. K. Sächs. Ges. d. Wiss.*, XXX, page 49, 1907, have been used. The ephemeris is calculated from the apparent coordinates of the Moon and the Sun, and therefore aberration is fully included, excepting the inappreciable difference between the light-time from the Sun to the Moon and from the Sun to the Earth.

The *Age* is the number of days elapsed since the previous New Moon. The *Fraction Illuminated* is the fraction of the area of the lunar disk that is illuminated, and is equal to the illuminated fraction of the diameter perpendicular to the line of cusps.

On the surface of the Moon, selenographic longitudes are measured from the lunar meridian that passes through the mean central point of the visible disk, positive in the direction toward *Mare Crisium*, i. e., toward the west on the celestial sphere. Selenographic latitudes are reckoned positive towards the north limb; that is, they are positive in the hemisphere containing *Mare Serenitatis*. The mean central point of the disk is defined as the point on the lunar surface where the surface is intersected by the radius of the Moon that would be directed toward the center of the Earth, were the Moon to be at the mean ascending node when the node coincided with either the mean perigee or mean apogee.

The tabular selenographic longitude and latitude of the Earth are the geocentric selenographic coordinates of the apparent central point of the disk; at this point on the surface of the Moon, the Earth is in the selenocentric zenith. These coordinates are the sums of the geocentric optical and physical librations in longitude and latitude respectively. When the libration in longitude, that is the selenographic longitude of the Earth, is positive, the mean central point of the disk is displaced eastward on the celestial sphere, exposing to view a region on the west limb. When the libration in latitude, or selenographic latitude of the Earth, is positive, the mean central point of the disk is displaced towards the south, and a region on the north limb is exposed to view.

The selenographic coordinates of the point on the lunar surface where the Sun is in the selenocentric zenith are the selenographic longitude and latitude of the Sun. Subtracting the selenographic longitude of the Sun from  $90^\circ$  or  $450^\circ$  gives the selenographic *colongitude* of the Sun tabulated in the ephemeris; numerically, it is the *east* selenographic longitude of the morning terminator, and is therefore approximately  $270^\circ$ ,  $0^\circ$ ,  $90^\circ$ , and  $180^\circ$  at New Moon, First

Quarter, Full Moon and Last Quarter, respectively. The longitude of the evening terminator differs by  $180^\circ$  from that of the morning terminator.

The position angle of the axis is the angle that the lunar meridian through the apparent central point of the disk towards the north lunar pole forms with the declination circle through the central point, reckoned eastward from the north point of the disk.

The column headed *Position Angle-Bright Limb* contains the position angles of the midpoint of the illuminated limb, reckoned eastward from the north point of the disk. They replace the values which before 1960 were given for the position angle of the terminator, defined as the position angle of the northern cusp, or angle that the line of cusps forms with the declination circle through the apparent central point of the disk. The position angle of the terminator always lies between  $-90^\circ$  and  $+90^\circ$ ; before Full Moon it is  $90^\circ$  greater, after Full Moon  $90^\circ$  less, than the position angle of the midpoint of the bright limb.

For accurate reductions of observations, the tabular librations and position angles of the axis should be reduced to topocentric values. The topocentric values may be obtained by means of differential corrections, for which formulae are given by ATKINSON, *Mon. Not. Roy. Astr. Soc.*, **111**, 448, 1951; or, alternatively, the topocentric optical librations may be obtained by direct calculation, and the tabular geocentric physical librations used without correction. The optical librations  $l'$  in longitude and  $b'$  in latitude may be calculated from the apparent topocentric longitude  $\lambda$  and latitude  $\beta$  of the Moon by the formulae

$$\begin{aligned} l' &= \lambda + \mu + Ab' - \mathfrak{C}, \\ b' &= B - \beta, \end{aligned}$$

in which  $\mu$ ,  $A$ ,  $B$ , are tabulated on pages 324–325 with argument  $\lambda - \Omega$ , and  $\Omega$  and  $\mathfrak{C}$  are tabulated on page 51; the topocentric values of  $\lambda$  and  $\beta$  are obtained by applying corrections for geocentric parallax to the apparent geocentric co-ordinates of the Moon. The position angle  $C'$  of the axis, affected by only optical libration, is determined by

$$\sin C' = \sin i \cos (l' + \Delta + \mathfrak{C} - \Omega) \sec \delta,$$

where  $\delta$  is the topocentric declination, and  $i$  and  $\Delta$  are tabulated on page 51; adding the tabular physical libration gives the topocentric position angle.

#### *Disks of Mercury and Venus (pages 326–327)*

Beginning with 1960, the position angle  $\Theta$  of the midpoint of the bright limb is tabulated instead of the position angle  $\theta$  of the line of cusps formerly given in these ephemerides. The angle  $\Theta$  is the position angle of the arc of the great circle from the planet to the Sun, while  $\theta$  is the angle which this arc forms with a great circle passing through the planet and directed toward the west. The angle  $\theta$  is measured from the westward directed great circle, through north, east, and south, from  $0^\circ$  to  $360^\circ$ . Therefore  $\Theta = \theta - 90^\circ$ ; the position angle of the greatest defect of illumination is  $\Theta + 180^\circ = \theta + 90^\circ$ .

*Ephemerides for Physical Observations of Mars, Jupiter, and Saturn*  
(pages 328-341)

These ephemerides give the time required for light to travel from the planet to the Earth, and the stellar magnitude and apparent diameter of the planet; and for the illuminated disk they give the position angle of the point of greatest defect of illumination, measured eastward from the north point of the disk, and the angular amount of the defect; the planetocentric angle  $i$  between the Sun and the Earth is also tabulated. In the ephemeris for Mars, the ratio  $k$  of the area of the illuminated apparent disk to the area of the entire apparent disk regarded as circular is included.

For Mars and Jupiter, quantities are given which determine the geocentric and heliocentric aspects of the planetographic coordinate systems on the surface of the planet, to which the markings on the disk are referred. The aspect of the disk depends upon the positions of the Earth and the Sun relative to the different areas of the surface of the planet, or equivalently upon the apparent positions of the Earth and the Sun on the planetocentric celestial sphere at the different points of the surface. To represent these positions, coordinate systems are defined on the planetocentric sphere, by the plane of the equator of the planet and the plane of its orbit, in the same way as right ascension and declination, and celestial longitude and latitude, are defined on the geocentric celestial sphere by the equator of the Earth and the ecliptic. Because of the mathematically indefinite radius of the celestial sphere, the same fundamental reference circles are defined on the geocentric sphere as on the planetocentric sphere by the orbital and equatorial planes of the Earth and the other planets.

On a planetocentric sphere, the apparent position of the Earth is diametrically opposite the geocentric position of the planet, and the Sun is opposite the heliocentric position. The planetocentric angular distance of the Earth from the equator of the planet, denoted by  $D_E$  and known as the planetocentric declination of the Earth, is numerically equal and opposite in sign to the geocentric angular distance of the planet from the plane of the equator of the planet. The ascending node of the orbit of the planet on its equator is the vernal equinox of the planet; the angular distance in the plane of the planetary equator from this point eastward to the great circle through the Earth and the celestial pole of the planet, denoted by  $A_E$ , is known as the planetocentric right ascension of the Earth, and is equal to the geocentric longitude of the planet measured in the plane of its equator from its autumnal equinox or descending node of its orbit on its equator. Similarly, the planetocentric right ascension of the Sun,  $A_S$ , is equal to the heliocentric longitude of the planet measured in the plane of its equator from its autumnal equinox; and the planetocentric declination of the Sun,  $D_S$ , is numerically equal and opposite in sign to the heliocentric angular distance of the planet from the plane of the planetary equator. The planetocentric longitude of the Sun, denoted by  $L_S$  and measured in the plane of the orbit of the planet from its vernal equinox, is equal to the heliocentric orbital longitude of the planet reckoned from its autumnal equinox; it is tabulated only for Mars.

Planetographic longitudes on the surfaces of Mars and Jupiter are reckoned from  $0^\circ$  to  $360^\circ$  in the direction opposite the rotation, that is, eastward on the celestial sphere. The zero meridian from which the longitudes are measured is defined by the adopted position of the pole and an adopted value for the longitude of the meridian that passes through the central point of the disk at a selected epoch. The adopted longitude of the central meridian at the epoch and the rate of rotation of the planet determine the central meridian at any other time. The rotation is referred to the ascending node of the orbit on the equator of the planet, and the period is therefore known as the sidereal period of rotation; it differs slightly from the actual period of rotation, because of the precession of the axis of the planet.

For Mars, the position of the north pole that is used in computing the physical ephemeris was adopted in 1909, and the zero meridian is defined by the tabular central meridian at Greenwich mean noon on 1909 January 15; but beginning with 1960, a period of rotation is adopted that differs from the value used before 1960. Consequently, from 1959 to 1960 there is a discontinuity in the tabular longitude of the central meridian, amounting to about  $-1^\circ$ . The adopted rotation elements of Mars are:

*North pole of Mars* (LOWELL and CROMMELIN, *M. N. R. A. S.* **66**, 56, 1905)  
At the beginning of the year  $t$ ,

$$\begin{aligned}\alpha_0 &= 21^{\text{h}} 11^{\text{m}} 10^{\text{s}}.42 + 1^{\text{s}}.565 (t - 1950.0), \\ \delta_0 &= +54^\circ 39' 27'' + 12''.60 (t - 1950.0).\end{aligned}$$

*Sidereal period of rotation* (ASHBROOK, *Astr. Jour.*, **58**, 145, 1953)

In Ephemeris Time,  $24^{\text{h}} 37^{\text{m}} 22^{\text{s}}.6689$ .

*Central meridian*, referred to the zero meridian of 1909

Longitude of central meridian,

$$1909 \text{ Jan. } 15, \text{ G.M.N. (J.D. } 241\,8322.0), 344^\circ.41.$$

Daily motion,  $350^\circ.891\,962$ .

The tabular central meridian is for the geometric disk, not the illuminated disk; and the time of transit of the zero meridian is for the transit across the central point of the geometric disk.

The position angle of the axis is the angle which the meridian from the central point of the disk to the north pole of rotation forms with the declination circle through the central point, measured eastward from the north point of the disk.

For Jupiter, the adopted position of the pole is derived from the position for 1750 given by DAMOISEAU, *Tables Écliptiques des Satellites de Jupiter* (Paris, 1836), page i; the longitude of the central meridian that defines the zero meridian, and the rate of rotation, are adopted from the ephemeris last published by MARTH, *Mon. Not. Roy. Astr. Soc.*, **56**, 523, 1896:

*North Pole of Jupiter*

At the beginning of the year  $t$ ,

$$\alpha_0 = 17^{\text{h}} 52^{\text{m}} 00^{\text{s}}.84 + 0^{\text{s}}.247 (t - 1910.0),$$

$$\delta_0 = +64^{\circ} 33' 34''.6 - 0''.60 (t - 1910.0).$$

*Sidereal period of rotation**Central meridian*

Longitude,

$$1897 \text{ July } 14, \text{ G. M. N. (J.D. } 241\,4120.0) \quad 47^{\circ}31' \quad 96^{\circ}58'$$

Daily motion

$$877^{\circ}90' \quad 870^{\circ}27'$$

	System I	System II
	9 <sup>h</sup> 50 <sup>m</sup> 30 <sup>s</sup> .003	9 <sup>h</sup> 55 <sup>m</sup> 40 <sup>s</sup> .632

System I applies to all points on or between the north component of the south equatorial belt and the south component of the north equatorial belt; System II applies north of the south component of the north equatorial belt, and south of the north component of the south equatorial belt.

The tabular central meridians are for the geometric disk; applying to them the corrections in the column headed *Correction for Phase* gives the longitudes of the central meridian of the apparent or illuminated disk. In addition, the longitude of the central meridian of the illuminated disk is tabulated at daily intervals in a separate ephemeris; the tables of the motion of the central meridian accompanying this ephemeris are based on the mean daily synodic rotations during the period when Jupiter is observable, which are  $877^{\circ}.95$  for System I, and  $870^{\circ}.30$  for System II. An accuracy of  $0^{\circ}.1$  for the central meridian of the illuminated disk is usually sufficient, and may readily be obtained from the daily ephemeris; interpolation in the 4-day ephemeris is less convenient, but may be made in the infrequent cases when an accuracy of  $0^{\circ}.01$  is needed.

**Satellites**

The ephemerides of the satellites are intended only for search and identification, not for the exact comparison of theory with observation; they are calculated only to an order of accuracy sufficient for the purpose of facilitating observations. They are corrected for light-time; the tabular values are directly comparable with observations at the tabular times. The value of the light-time used in calculating the ephemerides of the satellites is  $498^{\text{s}}.58$  for unit distance.

The apparent orbit of a satellite is an ellipse on the celestial sphere, with semimajor axis  $a/\Delta$ , where  $a$  is the apparent semimajor axis at unit distance in seconds of arc and  $\Delta$  is the geocentric distance of the primary. In the tables for finding the position angle  $p$  of the satellite relative to the primary, measured in the usual way from north toward east, and the apparent distance  $s$  from the central point of the disk of the primary, the factor  $F$  is the ratio of  $s$  to the apparent distance at greatest elongation, and therefore  $s = F \frac{a}{\Delta}$ . At the greatest elongations,  $p = P \pm 90^{\circ}$ , where  $P$  is the position angle of the extremity of the *minor* axis of the apparent orbit that is directed toward the pole of the orbit from which the motion appears counterclockwise. With  $P_0$  denoting an arbi-

trary fixed integral number of degrees near the value of  $P$  at opposition, the value of  $p$  at any time is expressed in the form  $p_1 + p_2$ , where  $p_1$  is the sum of the approximate position angle  $P_0 + 90^\circ$  at elongation and the amount of motion in position angle since elongation, and  $p_2$  denotes the correction  $P - P_0$ . In the tables of  $p_1$  the tabular entry for argument  $0^h00^m$  is the value of  $P_0 + 90^\circ$ . In calculating  $F$  and  $p_1$ , the value of the eccentricity of the apparent orbit at opposition is used; and consequently in the values of  $s$  and  $p$  which are derived from them, the effect of the variation of the eccentricity of the apparent orbit is neglected.

The differences of right ascension and declination, in the sense "satellite minus primary", are approximately

$$\Delta\alpha = s \sin p \sec(\delta + \Delta\delta), \quad \Delta\delta = s \cos p,$$

in which  $s \sin p$  and  $s \cos p$  are the rectangular coordinates of the satellite in the directions perpendicular to the circle of declination and along this circle, respectively.

#### *Satellites of Mars (pages 342-345)*

The ephemerides of the satellites of Mars are computed from the orbital elements given by H. STRUVE, *Sitzungsberichte der Königl. Preuss. Akademie der Wissenschaften*, 1911, page 1073.

#### *Satellites of Jupiter (pages 346-373)*

The ephemerides of Satellites I-IV are based on SAMPSON'S *Tables of the Four Great Satellites of Jupiter*, London, 1910; but they are computed in accordance with the procedures developed by H. ANDOYER, *Bulletin Astronomique*, **32**, 177, 1915, in which a number of approximations and modifications of the tabular procedures are made.

Beginning with 1960, the elongations of Satellite V are computed from circular orbital elements determined by A. J. J. VAN WOERKOM, *Astr. Pap. Amer. Eph.*, vol. XIII, Part I, 1950:

Epoch  $T_0 = 1903$  September 1.5 U.T. = J.D. 241 6359.0

Mean elongation at unit distance	249°55
Inclination to equator of Jupiter	24'1
Longitude of ascending node	82°5 - 914°62 ( $T - T_0$ )
Mean motion per mean solar day	722°63175 = 2°0073 10417
Mean longitude at epoch	194°98
Secular acceleration	$-0^\circ113 - 0^\circ0076 (T - T_0) + 0^\circ00035 (T - T_0)^2$

where  $T - T_0$  is reckoned in Julian years, and the longitudes are reckoned in the plane of the equator of Jupiter, from the ascending node of the mean orbital plane of Jupiter on the plane of the equator of Jupiter, as in the physical ephemeris.

The differential coordinates of Satellites VI and VII are computed from J. BOBONE'S tables, *Astronomische Nachrichten*, 6279, 321, 1937, and 6309, 401, 1937.

The configurations of Satellites I–IV are shown in graphical form, on pages facing the tabular ephemerides of the eclipses and other phenomena of the satellites. The central vertical band in each diagram represents the equatorial diameter of the disk of Jupiter; the relative positions of the satellites at any time with respect to the disk of Jupiter are given by the curves. Where a satellite is immersed in the shadow of Jupiter or occulted behind the disk, the curve is interrupted. In constructing these diagrams, the coordinates of the satellites in the direction perpendicular to the equator of Jupiter are necessarily neglected.

For eclipses, the points  $d$  of immersion into the shadow and points  $r$  of emersion from the shadow are shown pictorially at the foot of the right-hand page, for the middle of each month; and at the foot of the left-hand page the rectangular coordinates of these points are given, in units of the equatorial radius of Jupiter. The axis of  $x$  is parallel to the equator of Jupiter, positive toward the east, and the axis of  $y$  is positive toward the north pole of Jupiter. The suffix 1 refers to the beginning of an eclipse, the suffix 2 to the end of an eclipse.

*Satellites and Rings of Saturn (pages 374–389)*

The ephemeris of the rings of Saturn is computed from the elements of the plane of the rings determined by G. STRUVE, *Veröff. d. Universitätssternwarte zu Berlin-Babelsberg*, VI, 4, page 49, 1930. The apparent outer dimensions of the outer ring are according to H. STRUVE, *Pub. de l'Obs. Central Nicolas*, XI, page 226, 1898; the factors for computing the relative dimensions of the rings are from BESSEL, *Abhandlungen*, I, pp. 110, 150, 319, except those for the dusky ring which are based on the observations of various astronomers.

The ephemeris of the rings gives the quantities that determine the Saturnian positions of the Earth and the Sun referred to the plane of the rings, upon which the appearance of the rings depends; the tabular quantities are:

- $U$ , the geocentric longitude of Saturn, measured in the plane of the rings eastward from its ascending node on the mean equator of the Earth; the Saturnian longitude of the Earth, measured in the same way, is  $U+180^\circ$ .
- $B$ , the Saturnian latitude of the Earth referred to the plane of the rings, positive toward the north; when  $B$  is positive, the visible surface of the rings is the northern surface.
- $P$ , the geocentric position angle of the northern semiminor axis of the apparent ellipse of the rings, measured from north toward east.
- $U'$ , the heliocentric longitude of Saturn, measured in the plane of the rings eastward from its ascending node on the ecliptic; the Saturnian longitude of the Sun, measured in the same way, is  $U'+180^\circ$ .
- $B'$ , the Saturnian latitude of the Sun referred to the plane of the rings, positive toward the north; when  $B'$  is positive, the northern surface of the rings is the illuminated surface.
- $P'$ , the heliocentric position angle of the northern semiminor axis of the rings on the heliocentric celestial sphere, measured eastward from the circle of latitude through Saturn.

The ephemeris of the rings is not corrected for light-time; for comparison with observation, the light-time tabulated in the physical ephemeris must either be added to the tabular time or subtracted from the time of observation.

The ephemerides of the six inner satellites and of Iapetus are computed from the orbital elements determined by G. STRUVE, *Veröff. d. Universitätssternwarte zu Berlin-Babelsberg*, VI, Parts 4 (1930) and 5 (1933). The ephemeris of Hyperion is computed from the elements given by J. WOLTJER, Jr., *Annalen van de Sterrewacht te Leiden*, XVI, Part 3, page 64, 1928; and of Phoebe, from the theory by F. E. ROSS, *Annals of Harvard College Observatory*, LIII, Number VI, 1905.

For the eight inner satellites, the times of conjunctions and elongations, and tables for finding the approximate apparent distance  $s$  and position angle  $p$ , are given. On the diagram of the orbits of Satellites I–VII, the points of eastern elongation are marked as “0”; and from the tabular times of these elongations, the apparent position of a satellite at any other time may be marked on the diagram by setting off on the orbit the elapsed interval since last eastern elongation. For Hyperion and Iapetus, ephemerides of the differential coordinates are also included; and an ephemeris of differential coordinates is given for Phoebe.

In calculating the elongations and conjunctions, and the tables of apparent distance and position angle, solar perturbations are not included for any of the eight satellites; and for the five innermost satellites, the orbital eccentricity  $e$  and the inclination  $\gamma$  to the plane of the rings are neglected. However, the mean longitude  $L$  and mean anomaly  $M$ , calculated from accurate values of the orbital elements, and including for Titan the solar perturbations, are tabulated at 10-day intervals for the eight inner satellites, and with them are given the values of the elements that have large variations. From the orbital position of the satellite determined with these tabular values, and the Saturnicentric position of the Earth referred to the orbital plane of the satellite, values for the apparent distance and position angle may be calculated, and differential coordinates in right ascension and declination determined. For Titan, Hyperion, and Iapetus, ephemerides are given for the values of  $U$ ,  $B$ , and  $P$  defined and measured relative to the orbital plane in the same way as the values relative to the plane of the rings; and for Satellites I–VI, tables of  $F$  with argument  $u-U$  are included, where  $u$  is the orbital longitude of the satellite. The tabular values of  $L$  and  $M$ , and of  $U$ ,  $B$ ,  $P$ , are the actual values at the tabular times, not corrected for light-time.

The mean orbital longitude  $L$  and the true longitude  $u$  of the satellite, and the longitude  $\theta$  of the ascending node of the orbit on the plane of the rings, are measured from the ascending node of the ring-plane on the mean equator of the Earth;  $L$  and  $u$  are reckoned along the ring-plane to the node of the orbit, then along the orbit. The formulae and constants for obtaining the true orbital longitude  $u$  and the radius vector  $r$  of each satellite in 1960, and from them the apparent geocentric position relative to Saturn, are:

*Mimas*

$$u = L + 2^{\circ}303 \sin M + 0^{\circ}029 \sin 2M,$$

$$\frac{r}{a} = 1.0002 - 0.0201 \cos M - 0.0002 \cos 2M,$$

$$a = 255''.9, \quad \sin \gamma = 0.0265.$$

*Enceladus*

$$u = L + 0^{\circ}509 \sin M; \text{ the motion of } L \text{ in } 10^4 \text{ varies from } 2627^{\circ}311 \text{ to } 2627^{\circ}322,$$

$$\frac{r}{a} = 1 - 0.0044 \cos M,$$

$$u - \theta = 36^{\circ} + 263^{\circ}15 \text{ (J.D.} - 243 \text{ 6000.5)},$$

$$a = 328''.3, \quad \sin \gamma = 0.0004.$$

*Tethys*

$$u = L, \quad \frac{r}{a} = 1,$$

$$a = 406''.4, \quad \sin \gamma = 0.0191.$$

*Dione*

$$u = L + 0^{\circ}253 \sin M,$$

$$\frac{r}{a} = 1 - 0.0022 \cos M,$$

$$u - \theta = 214^{\circ} + 131^{\circ}62 \text{ (J.D.} - 243 \text{ 6000.5)},$$

$$a = 520''.5, \quad \sin \gamma = 0.0004.$$

*Rhea* (at opposition of Saturn)

$$e = 0.00118, \quad a = 726''.9,$$

$$u = L + 0^{\circ}135 \sin M,$$

$$\frac{r}{a} = 1 - 0.00118 \cos M.$$

*Titan* (at opposition of Saturn)

$$e = 0.02895, \quad a = 1684''.4,$$

$$u = L + 3^{\circ}317 \sin M + 0^{\circ}060 \sin 2M,$$

$$\frac{r}{a} = 1.00042 - 0.02895 \cos M - 0.00042 \cos 2M,$$

$$F = 1 - \frac{0.00817}{\Delta} \frac{r}{a} \cos (u - U).$$

The apparent rectangular coordinates referred to Saturnicentric axes, with the  $x$ -axis in the plane of the rings and positive toward the east, the  $y$ -axis positive toward the north pole of Saturn, are

$$x = \frac{a}{\Delta} \frac{r}{a} F \sin (u - U)$$

$$= s \sin (p - P),$$

$$y = \frac{a}{\Delta} \frac{r}{a} F \left[ \sin B \cos (u - U) + \cos B \sin \gamma \sin (u - \theta) \right]$$

$$= s \cos (p - P),$$

from which  $s$  and  $p$  may be determined, or  $\Delta\alpha$  and  $\Delta\delta$ .

*Satellites of Uranus (pages 390-392)*

The ephemerides of Ariel and Umbriel are computed from the orbital elements determined by NEWCOMB, *Washington Obs. for 1873*, App. I; of Titania and Oberon, from the elements by H. STRUVE, *Abh. d. K. Preuss. Akad. d. Wiss.*, 1912. STRUVE's elements of the plane of the orbits are adopted for all four satellites.

*Satellites of Neptune (page 393)*

The ephemeris of Triton is calculated from elements by W. S. EICHELBERGER and ARTHUR NEWTON, *Astr. Pap. Amer. Eph.*, vol. IX, Part III, 1926.

**Sunrise, Sunset, and Twilight (pages 394-401)**

The tabular times of sunrise and sunset are the instants when the true geocentric zenith distance of the central point of the disk is  $90^{\circ} 50'$ . With an adopted value of  $34'$  for the horizontal refraction, and  $16'$  for the semidiameter, the apparent zenith distance of the upper limb, neglecting parallax, is then  $90^{\circ}$ , and the limb is apparently on the astronomical horizon. The tabular times of the beginning and end of astronomical twilight are the instants when the true geocentric zenith distance of the central point of the disk is  $108^{\circ}$ .

The tabular values give the local mean times of the phenomena on the meridian of Greenwich for northern latitudes up to  $+60^{\circ}$ . No interpolation is usually made for the local times at other longitudes; the error from neglecting the variation with longitude is negligible, amounting to a maximum of  $2^m$  in latitude  $60^{\circ}$  North. To obtain the local *standard* time or zone time, increase the local time four minutes for each degree of longitude west of the standard meridian, or decrease the local time four minutes for each degree east of the standard meridian.

In a *southern* latitude, the time of sunrise, sunset, or beginning or end of twilight, is obtained for any date by entering the table with the same *numerical value* of the latitude, but for a date about six months earlier or later than the actual date, and applying a small correction to the tabular time; these dates and corrections are tabulated at the foot of the page. The periods during which twilight lasts all night in southern latitudes may be found by substituting for the northern latitudes the corresponding southern latitudes, and for the dates the corresponding dates taken from the foot of the page.

**Example**

On 1960 May 4, in latitude  $-38^{\circ}$ , required the times of sunrise, sunset, and beginning and end of twilight. November 6 is the corresponding date, northern latitude, and the correction is  $+13^m$ .

	Beginning of Twilight		Sunrise		Sunset		End of Twilight	
	h	m	h	m	h	m	h	m
Lat. $+38^{\circ}$ , Nov. 6 . . . . .	5	00	6	31	16	56	18	25
Auxiliary table . . . . .	+13		+13		+13		+13	
<hr/>								
Lat. $-38^{\circ}$ , Local mean time, May 4 . .	5	13	6	44	17	09	18	38

The tabular values are based on the "Tables of Sunrise, Sunset, and Twilight" published as a *Supplement to the American Ephemeris for 1946*. These tables provide for obtaining the times at any point on the Earth in any year of the twentieth century.

**Moonrise and Moonset** (*pages 402-433*)

The tabular times of moonrise and moonset are the instants when the true geocentric zenith distance of the central point of the disk is  $90^{\circ} 34' + S - \pi$ , where  $S$  is the semidiameter and  $\pi$  the horizontal parallax of the Moon, and  $34'$  is the adopted horizontal refraction; the upper limb is then apparently on the astronomical horizon.

The tabular times are for the meridian of Greenwich, and are given both for northern and for southern latitudes from  $+60^{\circ}$  to  $-60^{\circ}$ . To obtain the local mean time of moonrise or moonset at other longitudes that are 12 hours or less west from Greenwich, take out the tabular times for the given date and for the next following date; at longitudes 12 hours or less east from Greenwich, take out the times for the given date and for the date preceding. Subtract the time on the earlier date from the time on the later date; multiply the difference by the twenty-fourth part of the longitude in hours and decimals of an hour, positive if west, negative if east; apply the product as a correction to the tabular time on the given date to obtain the required local mean time. To obtain the standard time or zone time, increase the local time by four minutes for each degree of longitude west of the standard meridian, or decrease the local time by four minutes for each degree east of the standard meridian.

Examples

1. For 1960 January 2, find the standard time of moonrise and moonset at longitude  $145^{\circ}$  or  $9^{\text{h}} 40^{\text{m}}$  east from Greenwich ( $20^{\text{m}}$  west of the standard meridian) and latitude  $37^{\circ} 50'$  south.

	d	Moonrise		Moonset	
		h	m	h	m
For Lat. $-37^{\circ}8$ . . . . .	Jan. 1	7	45	21	30
	Jan. 2	8	51	22	09
Difference . . . . .		+66		+39	
Product of diff. by $-9.7/24$ . . . . .		-26		-16	
Local mean time. . . . .	Jan. 2	8	25	21	53
Reduction to standard time. . . . .		+20		+20	
Standard time. . . . .	Jan. 2	8	45	22	13

2. For 1960 July 10, find the Eastern Standard Time of moonrise and moonset at Washington, D. C., longitude  $77^{\circ}$  or  $5^{\text{h}} 08^{\text{m}}$  west, latitude  $38^{\circ} 55'$  north.

	d	Moonrise		Moonset	
		h	m	h	m
For Lat. $+38^{\circ}9$ . . . . .	July 10	20	46	6	37
	July 11	21	29	7	48
Difference . . . . .		+43		+71	
Product of diff. by $+5.1/24$ . . . . .		+9		+15	
Local mean time. . . . .	July 10	20	55	6	52
Reduction to standard time. . . . .		+8		+8	
Eastern Standard Time . . . . .	July 10	21	03	7	00

**Astronomical Observatories** (*pages 434-452*)

The list of optical observatories is followed by a list of radio observatories; and an *Index List* is given for finding observatories that are better known by special names than by their geographic location.

The latitudes in most cases are astronomical; but in some instances they have been determined by geodetic triangulation from other points. The geocentric coordinates  $\rho \sin \phi'$  and  $\rho \cos \phi'$  are calculated for the International Ellipsoid; the altitude is included in every case where it is known.

The last two columns on the right-hand pages contain the parallax constants

$$\begin{aligned}\Delta_{\alpha} &= -\rho \cos \phi' \sin 8''.80 \\ &= -426.64 \rho \cos \phi' \times 10^{-7}, \\ \Delta Z &= -\rho \sin \phi' \sin 8''.80 \\ &= -426.64 \rho \sin \phi' \times 10^{-7};\end{aligned}$$

the tabular values are in units of the seventh decimal. Formulae for parallax corrections in right ascension and declination, and for corrections to the equatorial rectangular coordinates of the Sun to eliminate parallax, are given at the foot of each righthand page.

**Tables** (*pages 453-481*)

A list of the individual tables is given in the *Contents*. With the exception of Table II, reference has been made to each of these tables in the foregoing descriptions of the ephemerides, and an explanation of the table given where it is not self explanatory.

Table I of Julian Day Numbers is explained in the section on the calendar.

Table II, for determining latitude and azimuth from observations of Polaris, includes the precepts for the use of the table at the foot of each page.

Table III, for the reduction of mean places from one epoch to another, is explained in the section on mean places of stars. Tables IV-VI relating to reductions for precession, nutation, and differential aberration, include precepts for their use, and are referred to in the section on Day Numbers.

The precepts for using Table VII to calculate geocentric coordinates are included with the formulae for the International Ellipsoid in the section on units and constants.

Tables VIII-XII for conversions of measures of time, and the Interpolation Tables XIII-XVII are self explanatory.

 Star constants, Besselian . . . . . 506  
 Stars, mean places . . . . . 288  
     reduction from equinox of 1950.0  
         to true equinox, Table IV . . 461  
     reduction of mean places . 50, 460, 509  
     reduction of mean to apparent  
         place . . . . . 506, 507  
 Sun, aberration . . . . . 500  
     longitude and latitude . . . . . 18  
     mean anomaly . . . . . 50  
     mean elements . . . . . 50, 498  
     mean longitude . . . . . 50  
     parallax . . . . . 18  
     radius vector . . . . . 19  
     rectangular coordinates, 1950.0. 42  
     rectangular coordinates, 1960.0. 34  
     reduction to apparent longi-  
         tude . . . . . 18, 499  
     right ascension and declination . 19  
     rotation elements . . . . . 517  
     semidiameter . . . . . 19, 500, 510  
     synodic rotations . . . . . 315, 517  
 Sun, physical ephemeris . . . . . 310, 517  
 Sunrise and sunset . . . . . 394, 527  
  
 Tethys . . . . . 376  
     apparent distance and position  
         angle . . . . . 380  
         elongations . . . . . 377  
         orbital position . . . . . 384, 526  
 Time, civil reckoning . . . . . 488  
     conversion to arc, Table XI . . . 474  
 Titan . . . . . 376  
     apparent distance and position  
         angle . . . . . 382  
         elongations and conjunctions . . 379  
         orbital position . . . . . 384, 526  
 Titania . . . . . 390, 527  
     apparent distance and position  
         angle . . . . . 390  
         elongations . . . . . 392  
 Transit of Mercury over disk of Sun . . 306

Triton . . . . .	393, 527	Uranus, elongation . . . . .	9
apparent distance and position		geocentric ephemeris . . . . .	218
angle . . . . .	393	heliocentric ephemeris . . . . .	174
elongations . . . . .	393	magnitude . . . . .	9
Twilight, astronomical . . . . .	394, 527	osculating elements . . . . .	177
Umbriel . . . . .	390, 527	Uranus, satellites . . . . .	390, 527
apparent distance and position		Venus, elongation . . . . .	8
angle . . . . .	390	geocentric ephemeris . . . . .	186
elongations . . . . .	392	greatest brilliancy . . . . .	4, 490
Universal Time, conversion of ephemerides to . . . . .	495	heliocentric ephemeris . . . . .	168
definition . . . . .	482, 484, 486	magnitude . . . . .	8, 327
determination . . . . .	482, 484, 487	mean elements, mean anomaly . . . . .	176
of meridian transit, calculation of . . . . .	495	Venus, illuminated disk . . . . .	327, 519
of Transit of First Point of Aries . . . . .	10	Vesta, geocentric ephemeris . . . . .	258, 505
reduction from, to Ephemeris Time . . . . .	viii	geocentric phenomena . . . . .	8
		magnitude . . . . .	9
		Year, length . . . . .	489, 499
		Zone time, definition . . . . .	488
